INDEX

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

1945

The date of publication of any case may be determined from the case number. The first two figures of each case number indicate the volume number, 31. The third and fourth figures give the number of the week, dating from January 1. The last figure gives the case number for the week. For example, Case 31251 is the first case for the 25th week of Volume 31.

- Abscess of liver, multiple, 31291
 - of lung, multiple, 31311
 - of pancreas, multiple, 31291
- periappendiceal, 31291
- tubo-ovarian, 31441
- Adenoacanthoma of pancreas, 31222
- Adenoma of bronchus, 31181
 - of pancreas, islet-cell, 31051
 - of parathyroid, 31091
- Adrenal gland, hemorrhage into, 31292, 31481
- Amyloidosis of kidney, liver and spleen, 31212
- Aneurysm, arteriovenous, cerebral, 31071
 - arteriosclerotic (abdominal) of aorta, with rupture, 31172, 31442
 - dissecting, with rupture of aorta, 31081, 31192, 31391
 - mycotic (aortic valve) of aorta, 31081, 31372
- Anomaly, congenital, diaphragm of jejunum, 31342
 - mediastinal cyst arising from esophagus, 31351
 - short esophagus, 31141
- Aorta, syphilis of, 31392
 - (See Aneurysm)
- Appendix, mucocele of, 31072

SURGICAL MANAGEMENT OF CARCINOMA OF THE MIDTHORACIC ESOPHAGUS*

Preliminary Report

RICHARD H. SWEET, M.D.†

BOSTON

IN OCTOBER, 1942, in an address given before the American Academy of Ophthalmology and Otolaryngology, I¹ made the following statement:

Adequate removal of a carcinoma located in the middle half of the esophagus precludes the possibility of performing an anastomosis within the chest for the restoration of continuity. In all these cases it is necessary to establish a cervical esophagostomy and a gastrostomy or enterostomy for feeding.

Two years later, as a result of increased experience with the transthoracic resection of carcinoma of the cardia and lower end of the esophagus, the field of resection followed by an anastomosis has been enlarged and a satisfactory technic for the removal of malignant lesions higher in the esophagus has been developed. The Torek procedure can therefore be discarded except in those relatively rare cases in which the lesion extends well above the aortic arch.

The Torek operation, originally described in 1913,² has had a limited use. There are two serious objections to this procedure. In the first place, if it is carried out according to Torek's original technic which involves cutting across the lower esophagus and not entering the abdominal cavity, two important groups of lymph nodes to which these tumors frequently metastasize are not removed, these are the subdiaphragmatic periesophageal nodes and the group found in relation to the left gastric vessels.

TABLE 1 Abdominal-Node Metastases in Carcinoma of the Esophagus (72 Autopsied Cases)

LOCATION OF TUMOR	NO. OF CASES	ABDOMINAL NODES	
		POSITIVE	NEGATIVE
Upper third (neck and upper chest)	24	1	23
Middle third	32	11	21
Lower third	16	8	8

(Fig. 1) As a result, the operation is hardly worth while because these nodes are so frequently involved (Table 1). If one takes into account the

additional fact that the resectability of carcinoma in the midesophagus is perhaps the lowest of any region in the body, being found in only 14 per cent of all patients seen,¹ the possibility of obtaining a cure or a reasonably long remission of symptoms is

FIGURE 1 The Most Frequent Sites of Lymph-Node Invasion in Cases of Carcinoma of the Esophagus (reproduced from Sweet,³ by permission of the publisher)

discouragingly remote. The principal hope in such cases is for worth-while palliation.

The second major objection to the Torek operation is that as a palliative procedure it is most unsatisfactory. The continuous discharge of saliva and mucus through the cervical esophagostomy stoma and the trouble attending the care and the use of the gastrostomy for feeding make the patients who have been subjected to this operation miserable

*From the Surgical Service of the Massachusetts General Hospital and the Surgical Service of the Palmer Memorial Hospital. Presented at the annual meeting of the New England Surgical Society, Boston, September 20, 1944.

†Instructor in surgery, Harvard Medical School; associate visiting surgeon, Massachusetts General Hospital; surgeon, Palmer Memorial Hospital and New England Deaconess Hospital.

and unhappy. If the use of a rubber-tube connection is attempted, there may be leakage around the tube, difficulty in keeping it adjusted and inability of the patient to eat anything but liquids because of the mechanical inadequacy of the system. Even if, after much effort on the part of the surgeon and with hope and fortitude on the part of the patient, an external plastic esophagus is constructed, the length of time required makes the procedure impractical. In some cases, by the time the patient is able to take a soft diet and swallow the food through such a tube, he is already suffering the effects of recurrent or metastatic disease.

TOREK PROCEDURE

Since January, 1940, Torek operations have been performed on 14 patients at the Massachusetts General and Palmer Memorial hospitals. There were 2 postoperative deaths and 12 survivals. In 4

esophagus (Fig 2). These results have been discouraging.

RESECTION FOLLOWED BY HIGH ESOPHAGOGASTRIC ANASTOMOSIS

New hope has arisen from the application of knowledge gained from a large experience with resection of the cardia and lower esophagus by the transthoracic route. As a result, it is now possible to perform a much more radical esophagectomy in such cases, including the removal of the lymph nodes below the diaphragm, and to restore immediately the continuity of the gastrointestinal tract by an esophagogastric anastomosis performed high in the chest.

Technic of Operation

With the patient lying on his right side, the eighth rib on the left is resected and the seventh, sixth and,

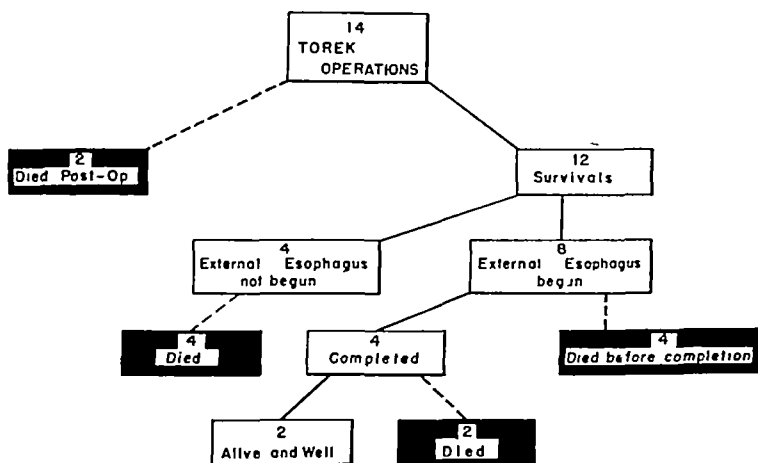

FIGURE 2 Experience with the Torek Operation at the Massachusetts General Hospital

cases, an external esophagus was completed, a connecting tube constructed from the skin of the chest wall with additional grafts from the thigh being utilized. This tube was used in 2 cases to connect the proximal esophagostomy opening above with a Beck-Jianu gastrostomy below. In 1 case, the lower esophageal end, pulled up to the anterior abdominal wall, was used as the lower stoma, and in 1 the fundus of the stomach and the stump of the esophagus were used after being pulled up under the skin of the chest wall.¹ Two patients died of metastases soon after the completion of the external esophagus. Two were alive and well 4 and 2 years, respectively, after operation. Of the remaining 8 patients, 4 died during the period of construction of the external esophagus—1 of pneumonia that did not respond to sulfonamide chemotherapy, and 3 of metastases or local recurrences. The remaining 4 patients have died of their disease without any attempt's being made to construct an external

if necessary, fifth ribs are divided posteriorly. This incision provides an adequate exposure to the region of the growth, and at the same time gives room enough below for incision of the diaphragm and mobilization of the stomach so that it can be brought up for an anastomosis high in the thorax.

Because of their location so close to several vital structures, such as the aorta, the inferior pulmonary vein, the left main bronchus and the left pulmonary artery, many of the tumors in this location are inoperable owing to direct invasion of these structures. It is therefore best to explore first the region of the growth. If one is careful, the possibility of completely mobilizing the tumor-bearing portion of the esophagus can usually be determined before division of any of the segmental esophageal arteries, which arise from the aorta. Once the resectability of the growth has been established, these vessels can be cut and the entire mass freed. In carrying out the mobilization of the growth, an opening into the

right pleural cavity is often made. At times it is necessary to remove a portion of the mediastinal pleura of the right side because of its adherence to the growth. The anesthetist's positive pressure prevents any serious degree of collapse of the right lung in such cases, and no attempt to close the opening need be made, because once the chest-wall incision is made airtight by its closure, there is no further danger of collapse of either lung unless lung tissue has been injured so as to permit escape of air from the alveoli.

After the midesophagus has been completely mobilized, the diaphragm is incised from the costal insertion through the hiatus. The upper portion of the stomach is then mobilized by dividing the post-

throughout its wall, especially at its upper portion. Furthermore, and for the same reason, the incision across the stomach must be at or just distal to the cardia, thus minimizing the danger of interrupting any anastomotic vascular channels within the stomach wall. Nevertheless, even in these cases one can with care remove the major portion of the lymph nodes around the cardia and from the region of the left gastric vessels.

Once the mobilization is complete, the stomach is cut across at or just below the cardia; its cut end is inverted, and a rubber glove is tied over the proximal end to avoid soiling the field of operation. If there is 5 cm or more of normal esophagus between the aortic arch and the superior margin of the

FIGURE 3 High-Esophago-gastric Anastomosis for Carcinoma of the Midthoracic Esophagus (reproduced from Sweet,² by permission of the publisher)

The esophagus has been completely mobilized and pulled out from behind the aortic arch. The stomach, after complete mobilization preserving the right gastric and right gastroepiploic vessels, is shown pulled high into the chest so as to make possible an anastomosis at or just above the level of the aortic arch.

cardial attachments, the vasa brevia, the gastrolienal and gastrohepatic ligaments and the left portion of the gastrocolic ligament. In all cases the ascending branches of the left gastric vessels must be severed to make it possible to swing the fundus far enough into the thorax to permit a high anastomosis.

In some cases in which the growth is unusually high, so that the esophagus must be divided close to or even above the aortic arch, it is necessary to divide the left gastric artery close at its origin and to cut the left gastroepiploic artery. I have proved by actual performance that this can be done with a successful outcome. The stomach must, however, be handled with great care to avoid trauma to any of the vessels that enter into the anastomosis.

growth, it is usually possible to perform an esophago-gastric anastomosis just below the aortic arch. If, on the other hand, the growth extends nearer to the arch, an anastomosis becomes impossible unless the esophagus is pulled up from behind and the anastomosis is performed in front of the aortic arch or at the level of its superior margin. In January of this year Garlock³ reported such a case. The usual three-layer, silk-technic anastomosis is performed, with excision of a circular piece of the wall of the fundus of the stomach. The technical details of this operation have been described elsewhere.^{4, 5}

This operation in cases of carcinoma of the mid-thoracic esophagus approaches more closely than anything previously available the ideal procedure for the radical removal of the tumor, including the

majority of the regional lymph nodes, for more satisfactory palliation in incurable cases, and for the obtaining of a better functional result

Experience in Carcinoma of the Midthoracic Esophagus

Since we have learned how to free the stomach sufficiently to bring the fundus to the level of the aortic arch or even above it, resections followed by high anastomosis have been carried out in 9 patients at the Massachusetts General and Palmer Memorial hospitals. In 5 of these cases, the upper limit of the growth was at a level that made it possible to perform an esophagogastric anastomosis just below the aortic arch. One of these patients died suddenly of what was apparently coronary thrombosis (permission for autopsy was refused)

this new operation, the last case mentioned is reported in detail

C K (M G H 444,523), a 63-year-old woman, was seen for the first time on May 17, 1944. For 4 months she had been having difficulty in swallowing, the trouble beginning with solids but gradually increasing until she could swallow nothing but liquids, even then she had to drink very slowly. She had lost a great deal of weight and strength.

Physical examination was essentially negative except for emaciation. The weight was 94 pounds. The heart sounds were regular and of good quality, with no murmurs. The blood pressure was 120/80. The diaphragm was low and moved only 1 cm. or less. Chest expansion was poor.

The patient was admitted to the Baker Memorial on May 19. On admission the white-cell count was 5400, the red-cell count 3,690,000, and the hemoglobin (photoelectric method) 11.0 gm. The nonprotein nitrogen was 32.5 mg. per 100 cc., the serum protein 6.0 gm., and the blood chloride 93 milliequiv. per liter. A blood Hinton test gave a negative reaction. X-ray examination revealed an ulcerating lesion in the middle

FIGURE 4 The Completion of a High Ante-aortic Esophagogastric Anastomosis (reproduced from Sweet,³ by permission of the publisher)

One is still in the hospital. The remaining 3 were doing well a few months to somewhat over a year from the date of operation.

In the remaining 4 cases, it was impossible to perform an anastomosis below the aortic arch, so that the upper end of the esophagus had to be mobilized and pulled up in front of the arch (Figs 3 and 4). The level of the completed anastomosis was at the superior margin of the aortic arch. Two of these patients died in the hospital, one because of sepsis resulting from tearing into an extremely adherent and actually inoperable growth during the operation, and the other because of coronary thrombosis (proved by autopsy). Of the 2 patients who survived the operation, one died subsequently of metastatic carcinoma, and the other recovered completely and resumed work.

As an illustration of what can be accomplished in cases of carcinoma of the midthoracic esophagus by

third of the esophagus, the appearance being consistent with a malignant tumor (Fig 5).

Esophagoscopy, performed by Dr. Edward B. Benedict, showed an annular, proliferating, nodular mass arising mostly from the left wall of the midesophagus, apparently not fixed and only partially obstructing the lumen. Its appearance was characteristic of carcinoma. Biopsy specimens were reported by the pathologist as epidermoid carcinoma, Grade III.

Intravenous infusions of glucose in saline solution and of amino acids (Amigen), as well as transfusions of blood, were given. The patient was able to take a high-calorie liquid diet. Parenteral vitamins were administered by the intravenous route. During the 48 hours immediately preceding operation sulfadiazine was given.

At operation, performed on May 27, an oblique incision was made across the left side of the chest and the 8th rib was resected. To obtain adequate exposure the 7th, 6th and 5th ribs were divided posteriorly. The growth was found lying in the esophagus and extending from just below the level of the aortic arch to a point opposite the inferior pulmonary vein. It was densely adherent to the areolar tissues over the aorta, and at one point it was necessary to cut so close to the aorta that one of the esophageal arteries was cut flush with its wall. The bleeding from this vessel had to be controlled by means of two sutures of arterial silk. After much painstaking dis-

section the growth was freed from the aorta. It was dissected from the hilus of the lung with greater ease, although there was a certain amount of adhesion to the structures just behind the left main bronchus. After the midportion of the esophagus had been freed all the way above the aortic arch, it was decided that a resection could be carried out.

After the phrenic nerve had been pinched, the diaphragm was incised. The spleen was freed from the stomach by cut-

ting the vasa brevia and the left gastroepiploic vessels, the former of which were extremely short. There were two or three enlarged, hard lymph nodes in the region of the left gastric vessels making it necessary to divide these vessels close to their origin to remove the nodes. Thus the stomach was entirely severed from its blood supply except for the right gastric and the right gastroepiploic vessels. A clamp was put across just distal to the cardia in such a way as to include all the involved lymph nodes in the excised portion. A second clamp was put on and the stomach was cut between them. A square of rubber dam was tied over the proximal cut edge. The distal edge was sutured, a fenestrated clamp being used. A second layer of catgut was used to invert the sutured edge, and a final layer of interrupted silk sutures was applied.

The stomach having been freed, it was possible to pull it up to a point just above the aortic arch. The esophagus was pulled up from behind the aortic arch and around in front of it. A circular incision was made close to the apex of the fundus of the stomach, and a three-layer, interrupted-silk, end-to-side anastomosis was carried out that after completion lay opposite the superior margin of the aortic arch. The stomach was fixed in the chest by interrupted silk sutures between it and the pleura lateral to the aorta. No attempt was made to close the opening that had been made in the right pleural cavity. The liver was palpated, nothing abnormal being found. The diaphragm was loosely attached to the stomach and the remaining portion of the diaphragm was closed. A catheter was led out through the lower part of the chest, its tip being placed behind the stomach in the right pleural cavity. A hole was made in the side of the catheter so as to drain the left pleural cavity and after the lung had been expanded the chest was closed, using silver wire in the 7th rib to help maintain rigidity. The remainder of the wound was closed with silk.

Pathological examination showed the specimen to consist of a previously opened segment of esophagus 11 cm long, with a 2 cm cuff of normal-appearing gastric mucosa. Five centimeters above the cardioesophageal junction was a firm ulcer 3 cm in diameter that completely surrounded the esophageal wall, its base was reddish-gray and granular. The mucosa-covered ulcer margins were raised and indurated. The cut surface was grayish white and granular, and the lesion extended into the surrounding fascia. The upper border of the ulcer was 2 cm from the esophageal incision line. In the portion of esophagus just distal to the main lesion there were several small, indurated, yellowish brown, submucosal nodules measuring 3 to 5 mm. There were many shaggy, yellowish gray lymph nodes measuring 1 to 2 cm scattered over the posterior aspect of the tissue, some of them hard and others cystic and necrotic on section. Eight of these were removed from various areas for section. Microscopical examination showed the tumor to be epidermoid carcinoma,

FIGURE 5 Roentgerogram (Patient C K)

The thoracic esophagus shows a filling defect caused by a carcinoma in the middle of the thoracic esophagus.

FIGURE 6 Resected Specimen (Patient C K) (reproduced from Sweet,³ by permission of the publisher)

This includes the esophagus, which contains the tumor, the cardia and a portion of the fundus of the stomach. Three groups of enlarged lymph nodes can be seen attached to the gastric end of the specimen.

Grade III, with metastases to the regional lymph nodes (Fig. 6).

The patient's immediate recovery from operation was uneventful. During the first 4 days she experienced enough respiratory embarrassment to require the continuous use of an oxygen tent, but after that time there was no difficulty and the convalescence was free from complications.

ting the vasa brevia and the left gastroepiploic vessels, the former of which were extremely short. There were two or three enlarged, hard lymph nodes in the region of the left gastric vessels making it necessary to divide these vessels close to their origin to remove the nodes. Thus the stomach was entirely severed from its blood supply except for the right gastric and the right gastroepiploic vessels. A clamp was put across just distal to the cardia in such a way as to include all the involved lymph nodes in the excised portion. A second clamp was put on and the stomach was cut between them. A square of rubber dam was tied over the proximal cut edge. The distal edge was sutured, a fenestrated clamp being used. A second layer of catgut was used to invert the sutured edge, and a final layer of interrupted silk sutures was applied.

The stomach having been freed, it was possible to pull it up to a point just above the aortic arch. The esophagus was pulled up from behind the aortic arch and around in front of it. A circular incision was made close to the apex of the fundus of the stomach, and a three-layer, interrupted-silk, end-to-side anastomosis was carried out that after completion lay opposite the superior margin of the aortic arch. The stomach was fixed in the chest by interrupted silk sutures between it and the pleura lateral to the aorta. No attempt was made to close the opening that had been made in the right pleural cavity. The liver was palpated, nothing abnormal being found. The diaphragm was loosely attached to the stomach and the remaining portion of the diaphragm was closed. A

The patient returned to work, and at the last examination, several months after operation, was well and had gained 12 pounds in weight.

Figures 7 and 8 are reproductions of postoperative roentgenologic films showing barium in the esophagus and stomach.

FIGURE 7 Roentgenogram (Patient C K)

This anteroposterior view, taken four months postoperatively, shows that the level of the esophagogastric anastomosis is considerably above that of the aortic arch and illustrates the fact that the major portion of the stomach lies within the chest.

The high level of the anastomosis opposite the manubrium of the sternum is shown especially in the lateral view (Fig. 8). Almost the entire stomach lies in the chest.

SUMMARY

The classic Torek operation is subject to the objections that it does not make provision for radical removal of the regional lymph nodes, which are so frequently invaded by disease, thus diminishing the possibility of obtaining a cure, and that it fails to provide satisfactory palliation because of the discomfort and unhappiness of the patient that result from the presence of a cervical esophagostomy and the necessity of being fed by gastrostomy. The construction of an external esophagus to connect the two stomas is a long and tedious process, usually performed in several stages, and can rarely be completed except in the most favorable cases.

Experience with 14 cases in which the Torek operation was performed is set forth.

Resection of the entire esophagus below the level of the aortic arch, followed by a high esophago-gastric anastomosis either just below or just above the level of the aortic arch, offers a more nearly ideal solution of the problem of the surgical removal of carcinoma of the esophagus, since it facilitates radical removal of the tumor, including the majority of the regional lymph nodes, and provides a more satisfactory degree of palliation in incurable cases and a better functional result.

A summary of the results of this operation in 9 cases is given, and a case is reported in detail as an illustration of what can be accomplished with this relatively new procedure.

During the interval of time that has elapsed since this paper was read before the New England Surgical Society, 11 additional patients have been subjected to radical operation for carcinoma of the middle half of the thoracic portion of the

FIGURE 8 Roentgenogram (Patient C K)

The lateral view, also taken four months postoperatively, shows that the esophagogastric anastomosis is opposite the manubrium of the sternum.

esophagus. In 3 of these the anastomosis was performed just below the aortic arch, and in 8 of them the growth extended so high that it was necessary to perform the anastomosis above

the aortic arch. Recovery was uneventful in 8 cases, complications occurred in 3, and these patients died. The causes of death in these cases were chylothous hydrothorax, empyema and cardiac failure, respectively. All deaths occurred in patients with high growths, which required anastomosis above the aortic arch.

The inclusion of these 11 additional cases makes a total series of 20 cases of carcinoma of the midthoracic esophagus with resection followed by high esophagogastric anastomosis. In 8 of these an anastomosis just below the aortic arch was performed, whereas in 12 it was necessary to relocate the esophagus and perform the anastomosis above the aortic arch.

In the entire series there were 6 deaths, a mortality of 30 per cent. Thirteen patients recovered and left the hospital in good condition, and 1 is still in the hospital.

DISCUSSION

DR. FRED B. LUND, Boston. This is one of the most brilliant presentations I have ever heard. Some years ago I had an opportunity to see at the Nose and Throat Department of the City Hospital all the cases of cancer of the esophagus that came there and of the 35 cases, 3 appeared to be operable. I operated on one patient through the chest, when I found that the growth had invaded the aorta, I did nothing more and the patient died. In the second case, I did a Torek operation, incising the pleura and sewing it up, the patient died. In the last case, I did a Lilienthal operation through the back and this patient also died. All these cases had presented poor prospects, but even so I was rather discouraged. Nevertheless I should have continued to operate if more operable cases had presented themselves.

DR. HARLAN F. NEWTON, Boston. It is well known to every one of us that the esophagus has been the "soft spot of the underbelly" of surgery. We have all heard and read of the splendid results in the surgical treatment of carcinoma of the upper third of the esophagus by excision that have in the past few years come from Canadian surgeons. Also, the lower third of the esophagus, attacked by cancer, has frequently been treated by excision with success. Dr. Sweet's paper deals with the surgical excision of carcinoma of the midesophagus, a tumor that has been considered up to this time as hopelessly inoperable. This makes his contribution outstanding and a pioneer piece of work.

The esophagus does not lend itself well to healing following operative trauma because of poor tissue resistance, friability, leaks following anastomoses, mediastinitis and other complications. Also of tremendous importance are the high degree of malignancy and the high incidence of early metastasis of practically every esophageal carcinoma.

Dr. Sweet is truly to be complimented both on this extraordinary series of cases so beautifully handled and for his modesty, for I know of no other such series of cases comprising

surgical excision of carcinoma of the midesophagus. We operated on a patient at the Peter Bent Brigham Hospital who has now gone about fourteen months without recurrence after complete resection of the carcinoma, this tumor originally appeared to be inoperable, but it was really at the junction of the lower and middle thirds of the thoracic esophagus.

Technically, excision of the midthoracic esophagus with mobilization of the stomach and anastomosis of the upper end of the esophagus to the stomach in front of the arch of the aorta is a brilliantly conceived, difficult achievement. It should stimulate all of us, particularly those interested in thoracic surgery.

I do not believe that we should even ponder on Dr. Sweet's results, and should certainly not criticize the mortality in his series. He is dealing with a lesion certain to kill and certain to kill rapidly. If he has extended any of these patients' lives and has increased their comfort, as is obvious from his results, surgery has been truly successful. In dealing with carcinoma of the esophagus in comparison to benign strictures there can be no choice between early one-stage esophageal anastomosis and multiple-stage surgery.

I think that Dr. Sweet considers this as only a preliminary report, in many ways a report of progress, but the fact that we have among us a man with courage enough to tackle this problem in a large series — and 9 is a large series — deserves commendation.

DR. DAVID CHEEVER, Boston. I wish first merely to pronounce the word "magnificent." During Dr. Sweet's discussion he uttered the words, "if you remember your anatomy." Dr. Sweet does remember his anatomy. I do not believe that he had to bone up on his anatomy before performing these operations.

Harvard Medical School students in the course of their instruction in anatomy have had called to their attention over many years the tremendous importance of the blood supply of the stomach and intestines. The points have been made that it is impossible to impair in the least degree the blood supply of the intestines and that, because there are so few anastomoses, one cannot resect freely, whereas in the stomach at least three fourths of the blood supply can be tied off the remaining fourth being sufficient to carry on the nutrition of the tissues, thus permitting extensive resections. Of course, it is this fact that, among so many others, Dr. Sweet has taken advantage of and that has made these magnificent results possible.

DR. RICHARD H. SWEET (closing). Both Dr. Newton and Dr. Fred Lund referred to operability, or at least implied that this was in their minds. Dr. Newton spoke about 9 cases being a large series, as a matter of fact, it is, because before we started doing this anastomotic work, I studied the operability of about 70 consecutive cases of carcinoma of the midesophagus that I had seen, and learned that only 14 per cent of the patients were finally subjected to a radical resection. Of course, the reasons for this are obvious. The principal one is the anatomic relation of the esophagus, these tumors lying opposite the pulmonary veins and arteries and the left main bronchus. Many actually invade these structures or the aorta.

With regard to entering the right pleural cavity, in case some of you wish to take up this type of surgery, the opposite pleura is frequently and of necessity opened, because, as you know, the pleura is reflected from both sides of the esophagus, but one need not pay any attention to this. One can open the right pleural cavity with safety, and nowadays I never bother to close it again, because the anesthetist has the situation under control.

I should like also to reiterate what Dr. Newton said. This is a preliminary report, and the whole subject is in a phase of development.

THE ANTITHROMBOTIC ACTION OF GELATIN*

Preliminary Report

HENRY HAIMOVICI, M D,† AND JACOB FINE, M D ‡

BOSTON

PROPERLY prepared gelatin is now regarded as a satisfactory blood substitute within certain limits for the treatment of traumatic shock.^{1 2} Intravenously administered gelatin, however, has been observed to produce an increased bleeding and clotting time in the experimental animal in deep shock.¹⁻³ This is also true of albumin and plasma.³ It occurred to us that if this were also a property of such fluids in the relatively normal state of the organism, they might prove useful in the prophylaxis or therapy of deep venous thrombosis, in place of heparin or dicoumarin, which have serious limitations. Of these fluids the most readily available is gelatin. This report deals with a preliminary experimental inquiry into the capacity of gelatin to prevent thrombosis in veins subjected to injury.

METHOD

The simplest method of producing thrombosis in a vein is by the use of a noxious chemical agent.^{4 5} Acceptable conditions for a study of the production of venous thrombosis by a chemical agent require that a given length of vein that has no branches be exposed to a given concentration of a given caustic agent for a given length of time. A sterile surgical technic is essential for this purpose.

Mongrel dogs weighing 8 to 10 kilograms were given morphine sulfate (10 to 20 mg per kilogram) or occasionally a 60 per cent Nembutal solution intravenously. Under novocain anesthesia the femoral or jugular veins or both were exposed aseptically. After 2.5 cm of each vein was carefully liberated from its sheath, two loops of thread were passed around it and the blood was gently milked from this segment. The vessel was then lifted by the threads, and into this temporarily isolated segment a quinine-urethane solution§ was injected through a 25-gauge needle and retained under slight tension within the lumen for periods varying from thirty seconds to five minutes. In most of the experiments a two-minute exposure was used. The fluid was then withdrawn into the syringe and the circulation re-established. At the completion of this procedure the wound was closed in two layers. Histologic examination of veins prepared as described, except for the actual injection of the quinine-

urethane solution, showed no injury to the intima or resulting thrombosis.

Intravenous pigskin gelatin solutions¶ were used exclusively. The various samples were fairly homogeneous in their simpler physical properties and chemical composition, with the following representative characteristics: dry weight, 7.17 per cent, ash, 0.95 per cent, sodium chloride, 0.85 per cent, reaction, pH 7.42, bloom, 41.0 gm, and viscosity, 3.4 at 37.5°C. Most of the solutions were autoclaved at 15-pounds pressure for forty-five minutes, and some for a longer period.

In the course of experimentation, twelve different preparations of gelatin were used. Eight of these exhibited definite antithrombotic action, whereas the other four, prepared somewhat differently, showed little ability to prevent intravascular clotting following injury. In the experiments reported below, only preparations known to be active were employed.

RESULTS

Control Experiments

In 13 dogs the intima of twenty-six veins was exposed to the quinine-urethane solution for thirty seconds. These veins were examined eighteen hours to six days after the operation. Ten veins (38 per cent) exhibited complete thrombotic occlusion, five (19 per cent) contained small nonoccluding thrombi, and eleven (42 per cent) were completely patent (Table 1). Failure to induce thrombosis uniformly in these experiments seemed to be due to the short exposure of the veins to the chemical injury. Accordingly, in subsequent experiments (thirty-one veins in 11 dogs) the exposure was increased to one to five minutes, in most of the experiments the time being two minutes. When the vessels were examined fifteen to forty-eight hours afterward, thrombosis was found in 84 per cent of the injured veins.

Macroscopic examination of the occluded veins showed at the site of injury a thrombus that, as a rule, did not propagate beyond the next proximal and distal branches. In only 2 cases was there found an extensive secondary clot, which in each extended from the jugular vein through the superior vena cava, right auricle and inferior vena cava and stopping at the hepatic veins.

Gelatin Experiments

In the experiments with gelatin the points under consideration were the volume and concentration

amount of gelatin was given four and a half to nine hours before injury, and in the third series, 25 cc of gelatin per kilogram of body weight was given one to three hours before injury In the fourth group, gelatin was given after injury to the veins The gelatin solutions were given intravenously in a single infusion lasting from ten to twenty minutes at the rate of 15 to 20 cc a minute

Gelatin injections before injury The first series included thirty-five veins in 17 dogs Thirty veins (86 per cent) were found to be entirely patent, and

seven and nine hours before injury, nine showed complete occlusion

In the third series, the least amount of gelatin necessary to prevent clotting was investigated Twenty-five cubic centimeters per kilogram of body weight was injected one to three hours before injury to the veins Of twenty-one veins in 7 dogs exposed to injury for two minutes, fifteen remained patent and seven were partially or wholly occluded

In summary, it appears that gelatin has a definite in vivo antithrombotic effect, that when gelatin is

given prophylactically in doses of 50 cc per kilogram at intervals of one to seven hours before injury to the vein, complete occlusion rarely occurs in veins exposed for two minutes to quinine-urethane, that better protection is afforded by a single intravenous injection of 50 cc per kilogram of body weight than by one of 25 cc, and that the protective effect falls off rapidly with time but persists for as long as seven hours.

Gelatin injections after injury In the fourth series of experiments, the animals received the infusion of gelatin from ten minutes to over four hours after injury to the veins. The results obtained, as recorded in Table 2, show that only 22 per cent of the veins remained patent, 24 per cent contained small, nonoccluding thrombi, and 53 per cent were completely occluded. Hence, gelatin provides no substantial benefit when given after injury to the veins.

To test the specificity of these results, the findings following the injection of another protein solution (bovine albumin) and of physiologic saline solution were observed.

Bovine albumin solution Fifty cubic centimeters per kilogram of body weight of a 5 per cent solution of crystalline bovine albumin* was injected intravenously one to eight hours before injury to twenty-eight veins in 10 dogs (Table 2). Of the injured veins, only seven (25 per cent) were patent. The remainder showed an almost equal percentage of partial (39 per cent) and complete (36 per cent) occlusions. No definite relation appeared to exist between the incidence of thrombosis and the interval between the infusion and the injury to the veins.

Saline solution Nine dogs, in which twenty-eight veins were injured (Table 2), received intravenous infusions of physiologic saline solution (50 cc per kilogram of body weight). The injections were given forty-five minutes to four hours before the vessels were injured. Only seven (25 per cent) of the veins were completely patent. Complete venous occlusions were found in 61 per cent, and partial occlusions in 14 per cent.

Although the percentages of venous occlusion were identical in both the albumin and saline series, complete obstruction in the saline series was almost twice that of the albumin series.

Hematologic Studies

Presumably the effect of gelatin on the thrombotic process involves an alteration in the blood constituents concerned with the coagulation phenomenon. This report deals only with the hematocrit and the bleeding, clotting and prothrombin times.

Hematocrit All hematocrit determinations were made on citrated blood in Wintrobe tubes, centrifuged at a 2500 r p m for thirty minutes. Blood samples were taken at various intervals before and

after the infusion, ranging over an average period of forty-eight hours. The hematocrit did not return to its initial level within this period except in a few cases. The following is a typical example.

TIME	HEMATOCRIT
	%
Before infusion	58.0
After infusion	
5 min	34.3
1 1/4 hr	43.0
4 1/2 hr	50.5
6 1/2 hr	52.0
23 hr	50.0
50 hr	52.0

Maximal hemodilution took place within the first six hours after gelatin infusion. The return of the hematocrit to a normal value is presumably correlated to the disappearance of gelatin from the blood stream, this varies from two to five days depending on the degree of degradation of the gelatin molecule at the time of infusion.⁶

Bleeding time The normal bleeding time in dogs, determined by pricking the animal's ear, was 2 to 3 minutes. Within ten to thirty minutes after the gelatin infusion, the bleeding time was appreciably prolonged. The maximal effect was present within half an hour after the infusion, but seven hours later the bleeding time was still three or more times normal. Return to a normal level was gradual, requiring more than twenty-four hours.

Clotting time Determinations of the clotting time were made at room temperature, before and after infusion, by the Lee and White technic. The blood was withdrawn directly from the exposed vein. The average normal clotting time in these dogs was about 3 minutes. After gelatin infusion the clotting time was found to be uniformly prolonged. In some cases the clotting time twenty-four hours after infusion was still twice as long as the control value, an observation at variance with the opinion⁷⁻¹⁰ that gelatin exhibits an *in vivo* coagulant effect.

Prothrombin time The prothrombin time was determined by Quick's technic, using rabbit brain thromboplastin, on whole and on diluted plasma (25 per cent and 12.5 per cent plasma in physiologic saline solution). The prothrombin time of whole plasma after gelatin infusion was normal, but that of dilute plasma was definitely prolonged. In some cases the prothrombin time twenty-four hours after the infusion had returned to its initial values, in others it was still prolonged.

Pathological Studies†

Specimens for pathological observations were taken at four and a half hours, at twenty-four to seventy-two hours and as late as seven days after injury to the veins, in both the control and the treated series.

In the control series histologic examination in the first twenty-four hours showed the lumen of the vein

to be filled with a fibrin thrombus containing platelets and red cells, there were a loss of endothelium, extensive degeneration of the media, occasional engorged vasa vasorum and hyperemia. At four days the picture was much the same, the vein wall appeared distended and few signs of regeneration were seen except for a few nuclei in the media or adventitia, which again took the stain.

In the dogs treated with gelatin, the patent veins examined one to five days after the injury showed the following changes in the vascular wall. In the first twenty-four to forty-eight hours, as a rule, the cells in the various layers of the vein wall showed a loss of nuclear staining, the engorged vasa vasorum, however, were virtually intact. After five days the vein wall exhibited signs of regeneration and repair of its different layers.

The pathological data are still incomplete, especially with reference to detail in the first few hours after injury and in the successive stages of the healing process in the treated animals.

SUMMARY

An adequate technic of inducing experimental venous thrombosis in dogs has been described. The ability of gelatin to prevent such thrombosis was investigated.

Eight out of twelve samples of gelatin exhibited a definite antithrombotic action when given prophylactically in a single injection. No beneficial

effect was obtained when the gelatin was given after injury to the veins.

The bleeding time and clotting time were appreciably prolonged after gelatin infusion. The prothrombin time of whole plasma was unchanged, whereas that of diluted plasma was definitely prolonged.

These data are of a purely experimental nature and should not form a basis for clinical application until more information has been obtained.

MEDICAL PROGRESS

GYNECOLOGY CARCINOMA OF THE ENDOMETRIUM

JOE VINCENT MEIGS, M.D.*

BOSTON

CANCER originating in the endometrial lining of the uterus has been given varied nomenclatures, such as "cancer of the fundus," "cancer of the body," "cancer of the uterus" and "cancer of the endometrium." Inasmuch as this tumor arises from the cells of the endometrium, it is proper to speak of it as cancer of the endometrium. This tumor is not so frequent as is carcinoma of the cervix, and, until far advanced, it is not nearly so lethal. At the Pondville Hospital since 1927 there have been approximately 1500 cases of cervical cancer and 300 cases of endometrial cancer, a ratio of 5:1. Watkins and Neilson¹ report 216 cases of cancer of the cervix and 43 of cancer of the endometrium, an identical ratio. Masson,² of the Mayo Clinic, writes that of 4407 cases of cancer of the uterus in their institution 3273 were of the cervix and 1134

of the endometrium, a ratio of about 3:1. There is a marked difference between the material from public hospitals and that from private practice. The number of cervical cancers is greater among the poor, and endometrial cancer is more frequently encountered in private practice. It is quite possible that, although clinic patients receive excellent obstetric care at the time of delivery, during follow-up the care of the cervix is not so complete and thorough as in the practice of the private obstetrician. This difference possibly explains the comparative absence of cervical cancer in private offices. There are of course differences in diet, hygiene and so forth that could be responsible, but the most obvious contrast lies in the more perfect care of the cervix of the private patient after delivery. Cancer of the endometrium is in most cases a comparatively mild type of tumor, but it can be extremely malignant and rapidly growing. Usually it is nonfatal while within

given prophylactically in doses of 50 cc per kilogram at intervals of one to seven hours before injury to the vein, complete occlusion rarely occurs in veins exposed for two minutes to quinine-urethane, that better protection is afforded by a single intravenous injection of 50 cc per kilogram of body weight than by one of 25 cc, and that the protective effect falls off rapidly with time but persists for as long as seven hours.

Gelatin injections after injury In the fourth series of experiments, the animals received the infusion of gelatin from ten minutes to over four hours after injury to the veins. The results obtained, as recorded in Table 2, show that only 22 per cent of the veins remained patent, 24 per cent contained small, nonoccluding thrombi, and 53 per cent were completely occluded. Hence, gelatin provides no substantial benefit when given after injury to the veins.

To test the specificity of these results, the findings following the injection of another protein solution (bovine albumin) and of physiologic saline solution were observed.

Bovine albumin solution Fifty cubic centimeters per kilogram of body weight of a 5 per cent solution of crystalline bovine albumin* was injected intravenously one to eight hours before injury to twenty-eight veins in 10 dogs (Table 2). Of the injured veins, only seven (25 per cent) were patent. The remainder showed an almost equal percentage of partial (39 per cent) and complete (36 per cent) occlusions. No definite relation appeared to exist between the incidence of thrombosis and the interval between the infusion and the injury to the veins.

Saline solution Nine dogs, in which twenty-eight veins were injured (Table 2), received intravenous infusions of physiologic saline solution (50 cc per kilogram of body weight). The injections were given forty-five minutes to four hours before the vessels were injured. Only seven (25 per cent) of the veins were completely patent. Complete venous occlusions were found in 61 per cent, and partial occlusions in 14 per cent.

Although the percentages of venous occlusion were identical in both the albumin and saline series, complete obstruction in the saline series was almost twice that of the albumin series.

Hematologic Studies

Presumably the effect of gelatin on the thrombotic process involves an alteration in the blood constituents concerned with the coagulation phenomenon. This report deals only with the hematocrit and the bleeding, clotting and prothrombin times.

Hematocrit All hematocrit determinations were made on citrated blood in Wintrobe tubes, centrifuged at a 2500 r p m for thirty minutes. Blood samples were taken at various intervals before and

after the infusion, ranging over an average period of forty-eight hours. The hematocrit did not return to its initial level within this period except in a few cases. The following is a typical example.

other etiologic factor should be clarified. It is well substantiated that cancer of the cervix is frequently found in women who have borne many children, whereas in endometrial cancer the reverse is apt to be true. Barns⁸ concludes that multiparas and primiparas are involved in equal numbers but that endometrial cancer comes in the unused organ and cervical cancer in the used. Radium or x-ray treatment as a reason for the occurrence of such growths must be considered. Luker¹² reports a case of his own and points out 14 others in the literature. There is no doubt that radiation may form the base of an epithelioma, for it often occurs on the skin following radiation treatment. Injury of the endometrium due to radium in the uterus may constitute the nidus of an epithelial growth, yet in many of the cases reported by Luker, the tumors came so soon after the radium treatment as to make one think that the tumor was present at the time of the curettage and was missed by the curette. Scheffey¹³ collected from the literature 71 cases of cancer following radiation, in 18 the cervix was affected, in 40 the endometrium, and in 13 the location was not stated. He added 20 cases — 7 of cancer of the cervix, 12 of cancer of the endometrium and 1 of myosarcoma. From his analysis of these cases he concludes that errors of omission in either technic or judgment and not the radiation therapy itself were the responsible factors in the subsequent occurrence of cancer. Randall,¹¹ however, reports 4 such cases a year after treatment with 1000 to 1800 mg hr of radium. Corscaden¹¹ in discussing Randall's paper states his belief that the radiation menopause has no therapeutic value in preventing cancer, but he doubts that it is a cause of cancer. He thinks that intra-uterine radium may be a cause of cancer in the uterine cavity, just as it may produce cancer on an epithelial surface in other parts of the body. Cancer of the cervix or upper vagina occurring five to ten years after previous proper treatment of a cervical cancer may be a recurrence or it may be due to the radium treatment itself, and the same applies to cancer of the endometrium.

The question of whether estrin is a responsible etiologic factor in the development of endometrial cancer has not been decided. It is the opinion of most gynecologists that treatment of the menopause in cases with the uterus intact should be carefully thought out, that the dosage of estrin should be small, that the drug should be withheld one week out of every month and that, if withdrawal bleeding occurs two weeks later, curettage should be performed. All authorities admit that estrin is a potent growth-producer and that in certain types of animals one can produce cervical and endometrial cancer. Important evidence is furnished by the facts that Smith¹⁴ has found thecal-cell hyperplasia in a number of cases of cancer of the endometrium, that I have recently observed it in the ovaries of a patient with cancer of the cervix and that many have noted

the frequency with which adenocarcinoma of the endometrium is present in patients with granulosa-cell or thecal-cell cancers of the ovary.

Most observers have rarely seen cancer of the endometrium in the castrated. Ingraham, Black and Rutledge¹⁵ note that Dr G Van S Smith has reported 3 cases of cancer of the endometrium occurring fifteen years after bilateral oophorectomy. The facts mentioned concerning fibroids, cancer and bleeding at the menopause, and also the fact that Randall¹¹ has noted the infrequency of hot flashes and atrophy in women with endometrial cancer, are significant. I have noted the absence of hot flashes in patients with cervical cancer who have received radiation. All these findings should make one hesitate to give estrin or diethylstilbestrol to every patient with a complaint, whether or not it can be attributed to the menopause. Ladin¹⁶ warns that it is not to be taken for granted that bleeding in the treatment of the menopause is due to estrin. Without confirmation by curettage, Scheffey, Farell and Hahn¹⁷ say that when abnormal bleeding is present during the later reproductive, menopausal and post-menopausal periods there is much less justification for prolonged endocrine therapy. They report cases in which endocrine therapy was introduced to control abnormal bleeding without preliminary examination to exclude organic pelvic disease, the result being a delayed diagnosis and treatment of uterine cancer. Corscaden, in discussing the above paper, states his belief that there is a relation between estrogen stimulation and the later development of cancer.

Ingraham, Black and Rutledge¹⁵ quote Dockerty as reporting 3 cases of cancer of the endometrium in 32 cases of granulosa-cell tumor and 1 in 10 cases of thecal-cell tumor, and conclude that the incidence of 10 per cent is more than coincidental. They themselves report 2 cases of endometrial cancer in granulosa-cell tumor and 1 in thecal-cell tumor of the ovary. In the discussion of this paper Stohr reports the case of a patient with cancer of the endometrium who simply had her granulosa-cell tumor removed and who on subsequent curettage had no cancer. Hertig¹⁸ states that at the Free Hospital for Women (Brookline, Massachusetts) at least 18 to 20 per cent of the patients with granulosa-cell tumors and thecomas have an associated carcinoma of the endometrium.

Novak¹⁹ reports a case in which a diagnosis of cancer of the endometrium was made following estrogenic treatment but in which subsequent curettage after cessation of treatment showed no cancer. Ingersoll²⁰ curetted a patient who had bled following estrogen treatment and the pathologist reported carcinoma of the endometrium, a subsequent curettage two weeks later showed no cancer and intrauterine radium treatment was given, six weeks later the uterus was removed and no cancer was found. Novak¹⁹ advises against prolonged and

the confines of the uterus itself but becomes fatal once it has grown beyond the walls of that organ

ETIOLOGY

The etiology of nearly all forms of cancer is still one of the great mysteries of the human body, and there is no evident cause for this particular type of growth. There have been many attempts to explain the presence of endometrial cancer and many suggestions to this end have been made, but none have thus far proved satisfactory. The late Dr. William P. Graves believed that endometrial cancer and possibly endocervical cancer was due to the irritation of retained secretions, owing to stenosis of the cervix. He thought that poor drainage caused by old cervical scars or cervical atrophy produced a definite irritation and chronic inflammation, and hence cancer. Chronic irritation, together with other factors, may easily have something to do with the formation of cancer. It is not infrequent that pyometrium is noted along with endometrial cancer, and the retention of pus, even though sterile, is almost certain to cause a severe irritation within the uterine cavity. On the other hand, pyometrium is often found in patients with cancer of the cervix and not infrequently in those whose cervical cancer has been treated with radium, yet cancer of the endometrium in these two conditions is extremely infrequent.

It is certain that chronic irritation is not the only cause of this type of cancer, although it is unquestionably present in some. It has been supposed that endometrial cancers may arise on a basis of endometrial polyps, just as intestinal cancer is so frequently found in patients with intestinal polyps. Hirson³ reported 4 cases in which polyps were found coincidentally with cancer of the endometrium or in which they had previously been removed. Ferris and Dockerty⁴ report such a case, and they discuss the criteria for determining that a cancer arises in a polyp: the carcinoma must be confined to one portion of the polyp, the base of the polyp must be benign, and the surface of the endometrium around the base of the polyp must show no malignant change. Their case fulfilled these criteria and must be accepted as a true adenocarcinoma in an endometrial polyp. It may be that other malignant polyps have been found, but it is certainly true that most endometrial polyps are benign and that most cancers of the endometrium do not arise in polyps. The supposed analogy to cancer of the large bowel is not a true one.

Frequently fibroids have been regarded as contributing in some way to the etiology of endometrial cancer. There is no doubt that fibroids are often encountered in patients with endometrial cancer, but by far the vast majority of them seem to have no relation to cancer. If fibroids are due to some abnormality in the reaction of estrin and its sister hormones, the possibility of an association is definite,

but a fibroid alone is not an etiologic factor. Masson and Gregg⁵ in a series of 590 patients who had been operated on found that 36 per cent also had fibroids. Miller⁶ found them in 20 per cent of his cases. Adair⁷ believes that 2 per cent of patients with uteruses containing fibroids have an accompanying cancer of the uterus and that 38 per cent of patients with cancer of the endometrium have fibroids. Barns⁸ found fibroids in 24 per cent. Watkins and Neilson¹ report fibroids in 38 per cent of their cases of cancer of the endometrium and believe that in some way these tumors are an etiologic factor. Healy⁹ found 40 per cent of his surgically treated patients with endometrial cancer also had fibroids, and thinks of this as more than a coincidence, believing that the presence of fibroids indicates that the uterus has tumor-growing possibilities. He advocates removal of the uterus in patients with fibroids over 5 cm in diameter. Scheffey, Thudium and Farrell¹⁰ found fibroids in 38 per cent of all patients treated surgically. Randall¹¹ believes that the consensus at the present time is that cancer of the endometrium develops just as frequently in a nonfibroid as in a fibroid uterus, and that the presence of a fibroid does not predispose to the development of cancer of the endometrium. His figures substantiate this. If one admits, however, that fibroids are in some way a development of abnormally functioning hormones, — as many surgeons do, — and if one looks at the results of Randall's excellent investigations, one is drawn toward the idea that uterine growths, including fibroids, are the effect of some fundamental disturbance that is also present in the formation of cancer of the endometrium.

Randall shows that patients with menorrhagia at the time of the menopause are three and a half times likelier to develop cancer of the endometrium later than are those who have an uneventful cessation of periods. His figures also show that only 8 per cent of women who did not develop cancer flowed beyond the age of fifty, whereas 35 per cent of those with endometrial cancer did so after fifty-one. No doubt many of these women had fibroids and therefore bled abnormally. He also states that many women with endometrial cancer have not had hot flashes, and do not have vulvar atrophy or senile changes of the vagina. He believes that there is a definite connection between granulosa-cell or thecal-cell tumors of the ovary — both of which produce estrin — and the presence of endometrial cancer. The last phenomenon has been noted by many authors.

All these findings considered together lead one to conclude that fibroids may not be an etiologic factor, but that they and endometrial cancers are produced just as are abnormal bleeding at the menopause and hyperplasia of the endometrium.

Before the evidence for and against a hormonal etiology of this cancer is given, the question of any

ment and who sixteen years later had the same type of tumor. These cases indicate the slow growth of some of the endometrial cancers, but there is always a question whether such patients had cancer or merely atypical hyperplasia.

PATHOLOGIC HISTOLOGY

Cancers of the endometrium are divided by some authors into adenoma malignum and adenocarcinoma. Grades I, II and III. Many omit adenoma malignum and believe that it really represents a Grade I adenocarcinoma. It is my belief that there is no such thing as adenoma malignum and that this nomenclature should be discarded. There is another epithelial tumor of the endometrium that is not often mentioned, namely, adenoacanthoma. This tumor is a combination of malignant adenocarcinoma and malignant squamous-cell carcinoma. It may occur in the endocervix and cervix, as well as in the endometrial cavity. Its treatment is the same as that for any cancer of the endometrium, except that it should never be treated with radium alone, since the results from such treatment are poor. Healy and Brown³⁶ believe that approximately half the endometrial cancers are adenoma malignum, one quarter adenocarcinoma, Grade II, and one quarter adenocarcinoma, Grades III and IV. Miller⁶ thinks that histologic grading helps in the prognosis but is only one of several factors, he is not impressed with the fact that Grades I and II are radiation-resistant. Corscaden³⁷ believes that tumor grading is less important in radiation cases than in hysterectomy cases. The pathologic histology of these tumors is important only in that they can be distinguished as slowly, moderately fast and rapidly growing tumors and as a combination of adenocarcinoma and squamous-cell carcinoma.

Carcinoma simplex is also reported, but this tumor may be simply an adenocarcinoma growing so rapidly that it is impossible for it to differentiate. Epidermoid cancer of the endometrium is found and probably arises in areas of metaplasia. Such areas are occasionally found in the normal uterus, and it is not difficult to believe that epidermoid cancer might originate in such an area.

SYMPTOMS

The chief symptoms of endometrial cancer are bleeding, discharge and pain. The bleeding may be profuse in the premenopausal period or at the time of catamenia, in the postmenopausal stage, the bleeding is often fairly continuous and small in amount. The discharge is watery and tinged with blood, both before and after the menopause. Pain indicates extension of disease and usually means a poor prognosis. Most patients with cancer of the uterus are in the postmenopausal age group, the

most frequent age period being fifty to fifty-nine. Kamniker³⁵ states that he did not find a single patient under thirty. Scheffey, Thudium and Farell¹⁰ assert that bleeding is the most significant symptom, having been present in 96 per cent of their series. Corscaden³⁹ found that of 201 patients one third had symptoms for more than one year and half for more than six months before the patients first went to their physicians.

DIAGNOSIS

The diagnosis is made on microscopic examination of the endometrium, either after the uterus is removed or after curettage. The removal of small specimens with the endometrial biopsy curette is not a satisfactory method of making the diagnosis. If the piece of tumor removed shows cancer, the diagnosis is made, but a negative report is not convincing. Ward⁴⁰ believes that diagnostic dilatation and curettage is the most valuable method of making the diagnosis and that early diagnosis is essential. Ladin¹⁶ states that in 1914 he reported 3 cases of cancer of the endometrium cured by curettage alone. Previous to his report 18 cases had been reported, and he therefore advises dilatation and curettage previous to operation. If there is a question concerning the presence of cancer in a given specimen, one should not rely on a frozen section but should wait until the tumor has been properly cut and studied. He is opposed to vaginal hysterectomy when cancer is suspected. MacFarlane, Sturgis and Fetterman⁴¹ report an early case in their yearly examination clinic in which the patient was well six years after radium and x-ray treatment, and one in which the patient after the seventh visit was found to have a symptomless fibroid and was operated on elsewhere by supravaginal hysterectomy, a small tumor being found just above the line of removal. The latter patient was well two years later. Supravaginal hysterectomy is not the proper treatment for cancer of the endometrium.

The history and a curettage were the only ways to make a diagnosis of carcinoma of the endometrium before operation until Papanicolaou and Traut⁴² in 1941 and Meigs, Graham, Fremont-Smith, Kapnick and Rawson⁴³ in 1943 demonstrated the practicability of vaginal smears in the diagnosis. Vaginal-smear diagnosis in carcinoma of the endometrium is not so accurate as that in cancer of the cervix. There is no question that the cells exfoliate, but diagnosis from the cells is more difficult. The best percentage of correct diagnosis by this method is between 80 and 85 per cent. According to Papanicolaou and Marchetti,⁴⁴ Bourgeois and Carv advised removing material for smears from the uterus by means of a suction apparatus, the former agree that this method has great possibilities. The use of the method of vaginal smears described by Papanicolaou will become of increas-

excessive treatment with estrogens after the cessation of ovarian function because of the frequent finding of endometrial hyperplasia and cancer. Crossen and Hobbs²¹ found that 60 per cent of women with uterine cancer still continue to menstruate after the age of fifty, whereas in a large number of women without uterine cancer menstruation occurs at this late age in only 15 per cent. According to an editorial in the *Journal of the American Medical Association*,²² these findings suggest that the long-continued action of ovarian hormones may be of significance in the origin of cancer not only of the mammary glands, the cervix and the vagina but also of the fundus of the uterus. Crossen and Loeb,²³ however, state that hormones alone are not responsible and that other factors must be present along with growth-producing factors. Randall¹¹ writes that Herrell studied the blood estrogens in women with cancer of the uterus in the postmenopausal period and reported no significant high levels. It is agreed, however, that the cause of hyperplasia of the endometrium is persistent, not high, levels of estrin. Jones and Brewer²⁴ found that of 19 premenopause patients with cancer of the endometrium 11 had cyclic menstruation, and of 9 operated on 8 had functioning corpora lutea. The ovaries may function normally and part of the endometrium may be normal. They believe that cystic changes in the ovaries are incidental and without significance.

From all this material it is evident that the estrins and similar preparations may be indicted in tumor production in both animals and human beings. Definite cancer production in the latter has not been proved, but there is enough suggestion of it to make one careful of excessive and prolonged treatment with estrin. Cancer of the endometrium does occur in patients before the menopause. Wallis²⁵ reports that Stacey found 36 per cent of his patients to be in the premenopausal stage, Norris and Dunne 30 per cent, and Masson and Gregg 33 per cent.

Cancer of the endometrium spreads by way of the lymphatics and blood vessels and possibly by the vertebral system of veins, as described by Batson.²⁶ The nodes involved are apt to be higher than those involved in cervical cancer—usually the upper iliac and lumbar nodes or those in the neighborhood of the kidneys. The vagina, the tubes and the ovaries are also attacked. The involvement of any of these organs makes for an extremely poor prognosis. Johnston²⁷ has advocated dissection and removal of the common iliac, uterine and external iliac nodes in doing a hysterectomy for cancer of the endometrium, but in my opinion this sort of procedure should accompany the operation for cancer of the cervix rather than that for endometrial cancer. Vaginal extensions have been noted by Strachan,²⁸ who believes that surface spread or submucous lymphatic infiltration is rare; he found vaginal metastases only in cases that were far advanced. In 90 cases, vaginal implants were noted in 12 and

no patient survived. I²⁹ found that vaginal metastases were not infrequent, noting them in 25 (12 per cent) of 206 cases at the Huntington Memorial Hospital. I believe that the extension is not an implantation but is a lymphatic metastasis by way of the cervix, which has a lymphatic connection with the uterus. This form of metastasis may be spread during hysterectomy, either by implantation in the raw vaginal cuff or by pressure on the lymphatics of the fundus. At the Pondville Hospital, radium treatment is given before operation, which is performed six weeks later, and in seven years there has been no case with a vaginal metastasis. The prognosis of patients with vaginal metastases is poor.

Involvement of the fallopian tubes and their role as paths of extension for cancer of the uterus to the ovary and cancer of the ovary to the uterus are discussed by Wallis²⁵ and by Lynch and Dockerty.³⁰ All these authors agree that cancer is found in the lumen of the tubes both free and implanted. Philipp and Huber³¹ report that in 16 of 62 patients they found extension into the tube. In 9 cases the tumor was free in the tube, and in 1 it was found on the surface of the ovary. Over twenty-six years ago Sampson³² advocated tying the ends of the tubes as the first step in hysterectomy, and also avoiding dilatation and curettage to prevent forcing cancer cells out through the tubes. Gentle manipulation of the uterus at examination in patients with suspected cancer of the endometrium is universally advised. Lynch and Dockerty³⁰ believe that the tubes are rarely the pathway of cancer extending to the ovaries or peritoneal cavity, but admit that this is possible. They conclude from anatomical studies that it is likelier that extension takes place by way of the lymphatics or by direct extension.

Involvement of the ovaries by cancer of the endometrium is a definite possibility, and in many hands these cases have done poorly. Barns³³ has reported that 7 of 95 patients had such involvement, and he believes that the prognosis is good, provided that there is no other extrauterine extension. This has not been my experience. Lynch and Dockerty³⁰ found that in 4 per cent of the operated cases of cancer of the endometrium one or both ovaries were eventually involved with cancer.

Brezina and Lindskog³⁴ report a total pneumonectomy for discrete tumor of the upper lobe of the right lung following hysterectomy for cancer of the endometrium, with removal of both tubes and ovaries, some years before. The patient recovered, and the tumor proved to be a metastasis from the cancer of the endometrium.

Barrows³⁵ operated on a patient with cancer of the endometrium who was given radium nine and four years before hysterectomy and who subsequently lived for six years in good health. Taylor, in discussing the paper, reported a patient who had had a dilatation and curettage for adenoma malignum at the age of forty-five, who had had no treat-

pregnancy and there is no extension, the five-year cures should be 60 per cent. Their five-year cures for 96 patients who could not undergo hysterectomy and were treated with radium was 39 per cent. It is therefore evident that five-year cures of at least 60 per cent should be obtained in the combined treatment of this disease.

CONCLUSIONS

Cancer of the endometrium is curable in a large percentage of cases.

The proper treatment consists of radium or x-ray or both, followed by total hysterectomy and bilateral salpingo-oophorectomy, with the removal of a large vaginal cuff, if possible.

Dissection of the lymph nodes has not as yet proved its value, but may do so in the future.

The diagnosis is best made by curettage, endometrial biopsy is not satisfactory.

Estrin in some form is possibly one of the etiologic factors. Endometrial polyps, unlike intestinal polyps, are probably not frequent etiologic factors.

The pathologic diagnosis of adenoma malignum should be discarded.

Cancer of the endometrium is extremely malignant once it has grown beyond the confines of the uterus.

ing value to clinicians as more and more laboratories are equipped to carry out proper interpretation of the slides

TREATMENT

Treatment of cancer of the endometrium may be surgical or radiologic or a combination of both. There is no doubt that nearly all workers in this field believe that the combination treatment is the most satisfactory. Thus, of sixteen writers on the subject, all but two agree that the results are better with the use of radiation and surgery. Three have employed vaginal hysterectomy to a large extent, and one of these always removes the ovaries at the time of the operation. Some prefer to use radiation exclusively, and all admit that good results can be obtained if it is properly given. Masson,² with the largest series, gives his immediate mortality for total hysterectomy in cases of endometrial cancer as 4.5 per cent, that for vaginal hysterectomy as 3.2 per cent, and that for subtotal hysterectomy as 9.2 per cent and that for radiation as 1.5 per cent. Healy and Brown³⁶ advocate not less than 3600 mc hr of intrauterine radium before operation and believe that 75 per cent of the patients so treated should survive for five years. Philipp and Huber³¹ prefer vaginal hysterectomy. All agree that the operative mortality following total hysterectomy should not exceed 2 per cent. Arneson⁴⁵ advises x-ray and radium for the operable group and x-ray and radium as for cancer of the cervix in the inoperable group. Crossen⁴⁶ believes that preliminary radiation decreases the chance of metastasis. He distributes the radium along a special wire apparatus or packs it in with detached units. Miller⁶ advises proper radiation, followed by total hysterectomy six weeks later. Johnston²⁷ recommends removal of the regional lymph nodes in addition to total hysterectomy. Kennedy⁴⁷ has never had a recurrence of cancer following vaginal hysterectomy by the clamp method when there was no involvement of the peritoneal coat at the time of operation. He speaks strongly against dilatation and curettage. Schmitz, Sheehan and Towne⁴⁸ found that of 11 patients receiving hysterectomy after full radium treatment 5 were free of cancer. Corscaden^{37, 39} believes that there is a chance for improvement in the method of radium application and in the order in which radium, x-ray and surgery are given. He thinks that 60 per cent of the patients operated on today should survive five years. He quotes Heyman as having consistently improved his percentage of cures until in his 1932-1935 group it was 63 per cent. Corscaden obtains some relief from the use of x-ray in pelvic and abdominal-wall extensions. He thinks that the combined treatment should give 80 per cent five-year cures. In his radiated cases 24 per cent showed no cancer when the uterus was removed. He quotes Farras as having 6 of 27 patients without cancer after radium,

Donovan and Warren 5 of 46, Martin 3 of 4 and Schmitz, Sheehan and Towne 4 of 5. Corscaden was able to keep 55 per cent of his patients well for five years with radium alone.

At the Pondville Hospital the uterus is measured with a hysterometer, and a gold radon tube is made that fits into a Monel applicator of the same measurement as the uterus. This is left in the uterine cavity long enough to give 3500 mc hr of radiation, and is followed by x-ray therapy, if desired. Total hysterectomy is done six weeks later. In few cases has all the cancer disappeared. In most cases the tumor shows marked injury and no vaginal metastases have occurred. It might be argued that six weeks' delay after radiation is too long a time, but with this delay no cancer had advanced beyond what it was before radiation was given, and usually the uterus is definitely smaller. In a few cases evidence of radiation reaction is found on the outside of the uterus or on the surface of the intestine, but no disaster has occurred since its use. Operation is no more difficult in those cases than in those in which radiation has not been given. If technically possible, a good-sized vaginal cuff should be removed. Both tubes and ovaries should always be removed. The dissection of the lymph nodes is not advocated at present, but after it has been done in more cases and the results have been reported it may easily become a part of the operation. For the inoperable cases x-ray and radium in full doses should be given. Great care should be taken to spread the radiation throughout the whole uterine cavity, for every part of it must be radiated if success is to follow.

The results of treatment vary. Arneson⁴⁵ found that the average five-year cures from surgery were 55 to 60 per cent and those from radiation in favorable cases 50 to 55 per cent. Miller,⁶ treating inoperable cases with x-ray and radium, kept 34 per cent of the patients well for five years. In the operable group his results from radium and total hysterectomy were 71 per cent cures for five years. Masson and Gregg⁵ effected cures for five years in 60 per cent of 711 cases and cures for ten years in 48 per cent of 520 cases. Smith¹⁴ reports 58 per cent of 307 cases cured for five years and 45 per cent for ten years. He believes that if a patient survives thirteen years after treatment of this disease, she is cured. Scheffey, Thudium and Farell¹⁰ effected five-year cures in 36 per cent of patients with surgery alone, in 41 per cent with radiation alone and in 38 per cent with surgery and radium. Corscaden³⁷ found that if the uterus was smaller than an eight-week pregnancy his results were 75 per cent cures for five years, a large uterus giving but 37 per cent results, and that if the cancer was beyond the uterus only 5 per cent of the patients survived five years. Healy and Brown³⁶ believe that adenoma malignum or low-grade cancer and adenocarcinoma give about the same results. If the uterus is not larger than a two-and-a-half-month

pregnancy and there is no extension, the five-year cures should be 60 per cent. Their five-year cures for 96 patients who could not undergo hysterectomy and were treated with radium was 39 per cent. It is therefore evident that five-year cures of at least 60 per cent should be obtained in the combined treatment of this disease.

CONCLUSIONS

Cancer of the endometrium is curable in a large percentage of cases.

The proper treatment consists of radium or x-ray or both, followed by total hysterectomy and bilateral salpingo-oophorectomy, with the removal of a large vaginal cuff, if possible.

Dissection of the lymph nodes has not as yet proved its value, but may do so in the future.

The diagnosis is best made by curettage, endometrial biopsy is not satisfactory.

Estrin in some form is possibly one of the etiologic factors. Endometrial polyps, unlike intestinal polyps, are probably not frequent etiologic factors.

The pathologic diagnosis of adenoma malignum should be discarded.

Cancer of the endometrium is extremely malignant once it has grown beyond the confines of the uterus.

BENJAMIN CASTLEMAN, M D, *Acting Editor*

EDITH E PARRIS, *Assistant Editor*

CASE 31271

PRESENTATION OF CASE

A sixty-five-year-old man was admitted to the hospital because of progressive malaise, anorexia, weakness, weight loss and swelling of the ankles.

The patient had been well and active as a shoemaker until about nine months before admission, when because of malaise and loss of strength he went to a physician. The patient was referred to a thoracic surgeon but failed to seek further medical aid until seven months later. Beginning nine months before admission the tips of the fingers and toes were observed to have become progressively larger. There had been no chest pain, cough, dyspnea or fever. He had experienced periods of pain in the fingers, elbows, hips, knees and ankles over this period. The ankles had swollen progressively since the onset of his illness and caused the most frequent joint pain. The knees became swollen on occasion. Aspirin brought considerable relief, but the taking of these tablets was followed by night sweats. His normal weight was about 125 pounds, and on admission he weighed 105 pounds.

Over the fifteen years before admission he had had vague joint pains that responded to aspirin, but these were unlike the pains experienced during the nine months before entry.

Physical examination revealed a well developed, pale, somewhat wasted and drawn man who was alert, co-operative and in no distress. The superficial veins were prominent over the entire body but were not distended. No superficial lymph nodes were felt. There was marked clubbing of the fingers and toes. There was moderate nonpitting edema of the ankles and feet bilaterally. The chest was symmetrical, with good expansion. The neck was normal. The lungs showed slight dullness to percussion and an area of tubular breathing at the right base posteriorly. There was a small area of dullness and diminished tactile fremitus over the left apex posteriorly. A few fine high-pitched rales were heard at the left posterior base. The heart and abdomen were normal, the liver and spleen not being palpable. A small right direct inguinal hernia was present. The joints of the hands, arms and legs were not enlarged

and showed no limitation of motion. The ankles were not red or hot.

The temperature was 100.0°F, the pulse 80, and the respirations 24. The blood pressure was 110 systolic, 60 diastolic.

Examination of the blood showed a white-cell count of 13,000, with 73 per cent neutrophils. The hemoglobin was 11.0 gm. The urine was normal but for an occasional red and white cell in the sediment. The serum nonprotein nitrogen was normal. The protein was 6.5 gm per 100 cc, the albumin-globulin ratio 1.2, the phosphorus 5.3 mg per 100 cc, the chloride 91 milliequiv per liter, the acid phosphatase 3.8 units per 100 cc, and the prothrombin time 36 seconds (normal, 18 to 20 seconds).

X-ray examination of the chest revealed a 10-by-9-by-9-cm shadow of increased density in the posterior portion of the base of the right lower lobe (Fig 1). The shadow appeared to be fairly homogeneous in density. An additional shadow measuring 3 by 2 cm was seen overlying the right third rib laterally. The remainder of the lung fields was clear. The diaphragm was low, and the right half showed some limitation in motion. The bones of the chest appeared normal. Fluoroscopy and Bucky films showed the mass in the right lower chest to move with the lung rather than with the ribs and over a fairly large portion of its circumference it was possible to see what appeared to be the inner surface of a wall. The smaller mass was not seen by fluoroscopy. An intravenous pyelogram was negative. Anechinococcus antigen skin test was negative. X-ray examination of the hands and feet showed extensive periosteal proliferation involving the distal extremities of the radius, ulna, tibia and fibula on both sides and several metatarsals and metacarpals.

After the first week the patient ran a low-grade fever. The clinical picture showed no further change. On the fifteenth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR ARTHUR J LINENTHAL. The discussion of this case seems to divide itself into two parts: the first is concerned with the primary diagnosis of what was obviously a tumor inside the chest, and the second with the associated hypertrophic osteoarthropathy and clubbing of the fingers, which the patient had to a striking degree.

Hypertrophic osteoarthropathy is apparently a disease similar in character to the process that leads to clubbing of the fingers, although it involves the more proximal joints of the extremities and gets its name from the fact that there are hypertrophic changes in the bone and disturbances in the joints. The symptoms of the hypertrophic osteoarthropathy that this patient manifested were somewhat more striking than what are usually seen. He had pain involving many of the joints. This pain was presumably much severer than the vague joint pains

*On leave of absence

that he had previously had. The joints themselves were not unusual on physical examination. There was no limitation of motion, no evidence of fluid, and in the ankles, where he had had the most trouble, there was absolutely no evidence of any acute process. He had moderate nonpitting edema of the feet and ankles. This apparently was not due to a collection of fluid, or it would have pitted, but undoubtedly was a manifestation of the hypertrophic changes in the soft tissue that are sometimes seen

DR GEORGE W. HOLMES: The striking thing in the films is the large, round, sharply defined tumor in the chest. The fact that the tumor is so round and smooth and so homogeneous in density puts it in a fairly definite group. I think it would be unlikely for a malignant tumor to reach that size and be as round and sharp. There is no evidence of interference with air flow in or out of the bronchi, and no evidence of involvement of the pleura. The tumor lies posteriorly, as you can see in the lateral

FIGURE 1 Roentgenogram of the Chest

Note the large round lesion in the lower portion of the right chest and the small lesion (arrow) over the right third rib

in this syndrome. The most striking feature of the osteoarthropathy is apparent in the x-ray films.

Clubbing of the fingers and hypertrophic osteoarthropathy can be seen in a great many conditions, but certainly the most frequent association is with diseases of the lung or related structures inside the chest, and undoubtedly that was the association in this case. As a matter of fact, the patient first went to a doctor, not because of pulmonary symptoms, but because of generalized symptoms of malaise, loss of appetite, weakness and weight loss, and at no time during his illness did he have any symptoms referable to the chest.

view. It would be interesting to speculate whether it contained fat. Dermoid cysts contain fat, and sometimes this can be shown by x-ray. I should say that this tumor does not show any evidence of fat.

The films of the leg and wrist show the characteristic appearance of pulmonary osteoarthropathy; in these cases these changes are the most striking near the ends of the bones.

DR LINENTHAL: What can be said about the small shadow in the upper part of the right chest?

DR HOLMES: I do not know what it is.

DR LINENTHAL: Could it be a metastatic lesion?

DR HOLMES: In other words, you would like to

think that they are both part of the same process and that the large tumor is also a metastasis?

DR LINENTHAL Could the smaller lesion be an unrelated metastasis from somewhere else?

DR HOLMES I question whether the large shadow could be a metastasis because of its size. The only tumors that metastasize like that are the sarcomas, and there is no evidence in this story that the patient had sarcoma elsewhere in the body.

DR LINENTHAL How much significance can be attached to the statement in the fluoroscopic note that it was possible to see the inside of the wall of the mass?

DR HOLMES They were speculating whether this was a cystic or a solid tumor. There are several ways of determining that information, none of which are particularly accurate. If you can see the inside of the wall, that usually means that the tumor is cystic. Sometimes it changes shape on respiration, and that is evidence that it is cystic. Both observations have to be taken with a grain of salt.

DR LINENTHAL We have then a large tumor in the chest, and the problem is to decide the nature of this tumor. There appear to be several possibilities. First is the question whether it arose from the chest wall. The observation on fluoroscopy that the tumor moved with the lung and not with the chest wall tends to rule out that possibility. Similarly, as Dr Holmes points out, there was no involvement of the pleura.

The second question is whether it was a primary lung tumor, and the complete absence of pulmonary symptoms suggests that such was not the case. Having eliminated these two possibilities we are left with the diagnosis of a mediastinal tumor, apparently arising in the posterior mediastinum and extending into the right side of the chest.

The next question is whether it was benign or malignant. Dr Holmes has mentioned that the general homogeneous smooth appearance suggests a benign lesion. One must pay close attention, however, to the clinical story, and in the same connection consider the question how long the lesion had been present. It seems likely that it had been there for more than nine months. The absence of respiratory symptoms suggests that it was a rather slowly growing process and one would like to suppose, therefore, that it had developed over an even longer period of time. In this connection the question of a congenital cyst might be raised, and although the patient was sixty-five years old, such a lesion is still a possibility. Then again we have some indication to suggest that there was a definite lesion in the chest nine months before admission, because at that time the patient was sent to a thoracic surgeon. It is interesting that the clubbing was first noticed nine months before admission, but presumably it had been developing for a longer period of time. Does this mean that the lesion in the chest began at that time, or that there was some change in a previously

existing lesion that had not caused clubbing but because of the change began to do so? I really do not know. The systemic symptoms began at the time the clubbing was first noted, nine months before admission, when he first noted weakness, malaise, anorexia and weight loss. This suggests either a malignant tumor or a low-grade infection, possibly associated with necrosis and hemorrhage inside a previously existing mass. When the patient came to the hospital he had a low-grade fever, a slightly elevated white-cell count and an anemia, which are consistent with either a malignant tumor or low-grade infection.

The small lesion in the chest is interesting and possibly important. It suggests metastatic disease. An intravenous pyelogram was negative, and although the urine showed an occasional red cell, I believe that the negative x-ray films rule out a renal-cell tumor giving rise to lung metastases. The normal acid phosphatase test is against a prostatic carcinoma with metastases to bone, which might also give metastases to the lung. Also there is no x-ray evidence of bone involvement. There is a possibility that the small lesion came from the larger one. There is no evidence of any other primary disease in the body that could have been the source of the smaller tumor. As Dr Holmes said, it is unlikely that the large lesion is metastatic.

The laboratory data are of no help. All the findings are normal except for the chloride, which was slightly low for no obvious reason, and the prothrombin time, which was definitely abnormal. There is no mention of jaundice, and nothing to suggest that this patient had liver disease. I imagine that the patient received vitamin K before operation. I wonder whether the prothrombin time was redetermined and whether there was any change.

DR BENJAMIN CASTLEMAN The test was repeated, and there was no change.

DR LINENTHAL Finally, the real problem in this case is the diagnosis of the pulmonary tumor. I do not believe that I am going to be able to make a definite diagnosis. All I am able to do is mention a few of the possibilities.

The lesion said to be most frequent in the posterior mediastinum is a tumor of neurogenic origin, a neurofibroma, which may go on to cystic degeneration and hemorrhage. I can see no way of being sure of such a tumor. This, I believe, may become malignant, but there is nothing in the x-ray appearance of the tumor to suggest that.

The possibility of lymphoma must also be mentioned, but the lesion is too smooth in outline and there is no way of being sure of that diagnosis unless one knew how it responded to x-ray therapy. A congenital cyst can occur at this age. I believe, however, that there is often x-ray evidence of attachment to or encroachment on the trachea or esophagus. There is nothing here to help in that respect. Another possibility is a tumor arising in other tis-

sues, such as a lipoma. Then, there is dermoid cyst, but I know no way of making this diagnosis unless one finds changes of density by x-ray or unless rupture into a bronchus leads to the raising of characteristic material. Furthermore, the patient is too old for such a tumor.

Echinococcal cyst was thought about, but the skin test was negative. It is, I think, positive in a high percentage of these cases.

I suppose one should always mention tuberculosis. It is interesting that on physical examination there was an area of dullness at the left apex, but the x-ray appearance of that region was apparently normal, so that I cannot see how one can go any farther.

I see no easy way of choosing between these possibilities. The best I can do is to put, as my first diagnosis, a tumor of the mediastinum, possibly cystic, with malignant degeneration, associated with hypertrophic pulmonary osteoarthropathy.

DR RICHARD H. SWEET: On the surgical service we have been impressed by the fact that extensive pulmonary osteoarthropathy seems to be associated more frequently with tumors of the lung and mediastinum, usually malignant ones, than with infections. Certainly I think that it would help you to exclude tuberculosis, benign cyst and dermoid cyst. I do not recall having seen osteoarthropathy with either of these conditions. The most extensive pulmonary osteoarthropathy that we have encountered has been in cases of carcinoma of the lung.

DR CASTLEMAN: Dr Herrera, will you tell us what you found at operation?

DR RODOLFO E. HERRERA: At the time of operation the small tumor in the upper chest wall proved to be a lipoma. The large tumor filled the entire right lower lobe. It had not extended to the chest wall, and so far as could be ascertained there were no enlarged lymph nodes in the mediastinum or in the hilus. The fissure between the middle and lower lobes was almost nonexistent, whereas it was almost complete between the middle and upper lobes. It was therefore much easier to remove the middle lobe with the lower lobe than to do a lower-lobe lobectomy, and this was done. The procedure also allowed the resection to be carried out far away from the tumor, which we believed grossly was a fibrosarcoma.

DR SWEET: I advised Dr Herrera to determine first the nature of the tumor in the chest. If it were a metastasis from the large tumor, pneumonectomy would have been unwise.

CLINICAL DIAGNOSES

Metastatic tumor of lung
Hypertrophic osteoarthropathy

DR LINTHALL'S DIAGNOSES

Malignant mediastinal tumor
Pulmonary hypertrophic osteoarthropathy

ANATOMICAL DIAGNOSES

Fibrosarcoma of lung
(Hypertrophic osteoarthropathy.)

PATHOLOGICAL DISCUSSION

DR CASTLEMAN: The specimen that we received was a large, round, well encapsulated tumor filling almost the entire right lower lobe (Fig 2). In places

FIGURE 2 Photograph of a Cross Section of the Resected Tumor in the Right Lower Lobe

it was necrotic. This turned out to be a fibrosarcoma. Whether this was a primary sarcoma of the lung or perhaps metastatic could not be determined grossly. I do not believe, however, that I have ever seen a metastatic tumor that had reached this size.

Do you want to tell us what happened after operation, Dr Herrera?

DR HERRERA: The patient had an uneventful postoperative course and was discharged at the end of the second week. From the first day after operation he was completely relieved of his joint symptoms. He volunteered the information that the stiffness and pain were completely relieved and remained so until about two months later, at which time his complaints were no longer centered in the extremities but along the spine and in the left lower quadrant of the abdomen. When x-ray films of the spine were taken, it was apparent that he had wide-

spread metastatic involvement of the vertebrae. There was a small nodule at the tumor end of the thoracotomy wound, which on removal showed recurrence of the fibrosarcoma. He went downhill rapidly and died of bronchopneumonia within three or four weeks.

DR HOLMES: The films that were taken later of the hands and wrist show much less evidence of periosteal reaction, apparently they improved. The appearance in the spine is not too conclusive, there is a mottled appearance, but before committing myself on that I should like to be sure that it was a constant finding.

DR SWEET: I have had one exception to Dr Castleman's statement that a single large tumor like this cannot be metastasis. In a patient whom I saw six or seven years ago there was a single metastasis this size in the right lung from a previously resected sarcoma of the breast. I wonder if sarcoma may not be an exception to that statement.

DR CASTLEMAN: I do not doubt that a metastasis can reach this size, but I do not believe that I have ever seen one.

Unfortunately we were unable to get permission for an autopsy and do not know whether the lesions in the spine were metastatic.

DR HOLMES: You still do not know whether the one in the lung was metastatic?

DR CASTLEMAN: Clinically he had no evidence of a primary tumor elsewhere.

DR MARIAN W. ROPES: The rapidity of the disappearance of bone and joint symptoms is extremely interesting. It came within a few hours after the operation. It is interesting to determine how soon the bone changes disappeared. These films were taken two months after operation and show considerable regression of the osteoarthropathy.

DR HOLMES: Do the periosteal changes completely disappear?

DR ROPES: According to the literature that has occurred. We have never had an opportunity to follow them completely enough to see. It is unfortunate that we did not have the chance to see the histologic appearance of the bones in this case.

I agree with Dr Sweet that the severest pulmonary osteoarthropathy that we have seen has been in cases of malignant disease rather than in cases of infection.

CASE 31272

PRESENTATION OF CASE

A seventy-four-year-old man was admitted to the hospital because of abdominal distress and hematemesis.

The patient was well until a week before admission, when he began to notice abdominal fullness

after eating. Flatulence gradually increased, and he became moderately anorexic and experienced periodic nausea. He had a normal bowel movement on the day before admission. On the day of entry he felt more distress than usual. He drank a "rum coke," then went to see his physician. En route to the physician's office he became acutely nauseated and vomited once. While in the office he repeatedly vomited dark fluid containing blood and had an episode of severe agonizing pain radiating from the epigastrium through the lower abdomen to the back and legs. While vomiting he fainted, fell and struck his head on the floor, bruising the left side of the face. He was taken promptly to this hospital.

He had had malaria fifty-three years before entry. He had had pneumonia on two occasions, once fifty-two years before entry and once nineteen years before entry. Six years before admission he had an appendectomy, with drainage, for a perforated appendix. Complicating abdominal-wall and scrotal abscesses were incised and drained. The post-operative period was also thought to have been complicated by a transient toxic hepatitis. He was discharged well five weeks after admission. Three and a half years before admission the patient had had a cholecystostomy for empyema of the gall bladder. At that time a blood Hinton test was positive but a Wassermann test was negative. After three weeks in the hospital he was discharged with a small draining sinus. This ceased to drain a few weeks later, and he remained well until the present illness.

Physical examination revealed a thin man with extremely pale skin and mucous membranes. There were massive periorbital and subconjunctival hematomas on the left side. The abdominal scars were well healed, a moderately sized defect of the abdominal wall was noted below the paramedian incision. Vision was poor. The eyes reacted to light and distance. The heart and lungs were normal. Abdominal examination was essentially negative. There was no tenderness or spasm. No organs or masses were felt. Peristalsis was normal. Rectal examination revealed a normal prostate and no masses or tenderness. A glove specimen of feces was soft and dark and gave a + + + + guaiac test.

The temperature was normal, the pulse 80, and the respirations 20. The blood pressure was 160 systolic, 80 diastolic.

Examination of the blood showed a white-cell count of 18,300. The urine gave a + test for albumin and a green reaction with Benedict's solution, the sediment contained 25 white cells, 2 to 3 red cells and many hyaline and granular casts per high-power field. The serum nonprotein nitrogen was 36 mg per 100 cc, and the protein 5.6 gm. The chloride and bilirubin were normal. The prothrombin time was 24 seconds (normal, 18 to 20 seconds).

An x-ray examination of the skull showed a fracture of the base of the left zygoma and a fracture of the root of the left maxillary antrum, with depression and clouding of the antrum. There was a questionable fracture of the roof of the left orbit, without additional deformity. In the right occipital area there was an indistinct line of decreased density running in a longitudinal direction for about 9 cm. A barium enema was negative. X-ray examination of the chest was negative, and no free gas was seen below the diaphragm. A gastrointestinal series showed a normal stomach and esophagus by fluoroscopy. The duodenal cap was slightly irregular, and no crater was seen with the fluoroscope. On the film, the duodenal cap showed an area in which the barium pooled, suggesting a crater. A plain film of the abdomen on the next day showed a large amount of barium remaining in the dilated stomach. This dilatation was not present at the time of the gastrointestinal examination on the previous day. There was a small amount of barium in the small bowel, and the colon was fairly well outlined.

At 3:00 a.m. on the third hospital day the patient became apprehensive. The skin was cold and clammy. He complained of severe pain in the abdomen, but this was negative on examination. An hour later he vomited forcefully a large amount of reddish-brown, foul-smelling fluid and the blood pressure was 130 systolic, 75 diastolic. He continued to vomit and passed a soft reddish-brown stool. The vomitus and the stool showed ++++ guaiac tests. At 6:00 a.m. he went into shock, becoming momentarily pulseless and very dyspneic. He vomited again and promptly appeared considerably better, with a strong pulse of 70 and a blood pressure of 130 systolic, 60 diastolic.

At 6:00 p.m. on the fourth day he appeared somewhat improved, with normal temperature, pulse and respirations. About two and a half hours later he was found to have expired. He had passed a moderate-sized, dark-red, tarry stool.

DIFFERENTIAL DIAGNOSIS

DR. GEORGE MARKS: There is evidence of a variety of lesions in this history. Through it all runs the theme of normal temperature, pulse and respirations, up to practically the last gasp. The question is, Which of the many lesions accounted for his sudden death? The past history contained numerous fairly major episodes: malaria, a drained appendix, cholecystostomy and a positive Hinton test. Yet it says in the beginning that he had been well until a week before admission. Apparently there was no particular loss of well being, at least from the last previous episode to his present entry. He obviously was sick when he arrived, in spite of the temperature, pulse and blood pressure, which presumably was not that of shock, although of course he may have been running a considerably higher pressure before

he arrived in the hospital. At entry the pressure was 160 systolic, 80 diastolic.

The first point that seems to carry a good deal of significance is the initial attack in the doctor's office, following a week of gradually increasing abdominal distress. Apparently in the beginning it was not an actual pain as much as a feeling of fullness and discomfort. It was somewhat periodical, and the patient had occasional nausea. He had an acute incident, in that he fainted, fell on his face and head and suffered fractures. I assume from the record that he was not unconscious when he arrived in the hospital, although that is not brought out specifically. The blood pressure and pulse do not indicate any change in intracranial pressure. So I am going to disregard the acute accident among other things, considering that it had no particular bearing on his death.

He was promptly x-rayed. The stomach was found to be negative, but there was a suggestive lesion in the duodenum at the first examination and at a subsequent one. I presume the second one was a twenty-four-hour plate. I have been told by the x-ray experts that films are of much less value than fluoroscopy, but I should like to see the films.

DR. MILFORD D. SCHULZ: I think that this is probably what was interpreted as a duodenal ulcer. There are no spot films, since we have to depend on the fluoroscopic observation in this day of film shortage. Only a single film of the stomach was made. Certainly there is a marked change in the appearance of the stomach in the film taken the following day. The stomach is greatly dilated, and there is a large amount of residual fluid and barium within it.

DR. MARKS: The question resolves itself into whether this man could have run the course that he did from hemorrhage from such a lesion as a duodenal ulcer. On examination he is described as having a negative abdomen, which he might have had if it were only a small hemorrhage. A large amount of blood in the intestinal tract will produce tenderness and generalized discomfort on palpation, but he apparently did not have those signs. He was not distended. During the course of the first three or four days in the hospital he developed gastric distention and pain, which was relieved by vomiting, this fits in with the distention that caused a disturbance of his intestinal tract from the duodenum on down.

Going back again to his initial attack of pain, the one that was so agonizing that he fainted and fell, I think the possibility of pancreatitis has to be considered. On the other hand, if pancreatitis were present and produced that much pain I should expect that something would have been found on physical examination. Apparently the abdominal examination did not bear out a fulminating pancreatitis.

Did he have a pin-point perforation of an ulcer, with a little fluid escaping now and then? That is possible, and between the escape of fluid he could have had a relatively negative abdomen. Yet, a pin-point ulceration of that sort, even when perforated, does not lead to sudden death.

Shall we pay any attention to the gall-bladder history? There is one point in the laboratory findings, the slightly lengthened prothrombin time, that perhaps represents some disturbance of liver function. Since it was not marked, since the blood bilirubin was not high and since the patient apparently was not jaundiced, it may have been secondary to his general condition. The urinary findings, to my inexperienced eye, could represent his seventy-four years, with nephrosclerosis.

There is perhaps one thing that covers his major disorder as well as any, namely, a dissecting abdominal aneurysm. Its first appearance was perhaps before the attack in the doctor's office, which represented the beginning of dissection, later there was disturbance of the innervation of the intestinal tract, and possibly the circulation. I should expect, however, that he would have had more local abdominal signs if he had had a circulatory disturbance of the intestine. I have to consider mesenteric thrombosis, although mesenteric thrombosis certainly has local signs.

I visualize this sequence of events as a dissecting aneurysm that at first progressed slowly and then involved the duodenum, the portion of the intestinal tract that overlies the aorta retroperitoneally, with eventual rupture causing sudden death. There is nothing in the physical examination referring to nerve or circulatory changes in the lower extremities, the blood pressure readings and so forth?

DR BENJAMIN CASTLEMAN: None were observed.

DR MARKS: It seems to me that this case is one of death from hemorrhage, and to my way of thinking we have not enough evidence of sudden intra-intestinal or intragastric hemorrhage to explain the picture on that basis.

Sudden hemorrhage may occur from gastritis. Whether the taking of a "rum coke" on the way to the doctor's office was a habit or just to bolster up his morale we do not know. Acute gastritis following bouts of alcoholism can produce massive bleeding. My impression from the history is that there was not a great amount of actual blood, although blood was constantly found in the contents of the stomach and large intestine. I shall rest the case by saying that this was a dissecting aneurysm with final rupture. He had had one positive Hinton test, but whether or not the aneurysm was syphilitic in origin I shall not attempt to say. The x-ray picture may represent ulcer, although I am inclined to believe that the spasm noted by x-ray in the duodenum was secondary to the retroperitoneal lesion.

CLINICAL DIAGNOSIS

Carcinoma of stomach?
Coronary thrombosis?

DR MARK'S DIAGNOSIS

Dissecting aortic aneurysm, with rupture

ANATOMICAL DIAGNOSES

Duodenal ulcers, bleeding
Acute and chronic gastritis
Hemorrhage into the gastrointestinal tract

PATHOLOGICAL DISCUSSION

DR. CASTLEMAN: At autopsy this patient's stomach was filled with about 700 cc of fresh clotted blood and the entire gastrointestinal tract was also filled with blood. There were probably two sources for the hemorrhage. He had two duodenal ulcers just beyond the pylorus, one of which was an obvious source of the bleeding, the other source may have been the severe gastritis, which involved almost the entire mucosa. The mucosa was markedly injected, raised and pebbly. I believe that most of the bleeding, however, originated from the duodenal ulcer. That was the complete story.

DR MARKS: How do you explain the pain in the back and down the middle of the leg?

DR CASTLEMAN: Dr Jones has described pain in the back in the duodenal ulcer. I cannot explain the leg pain.

DR MARKS: Was the ulcer on the posterior wall of the duodenum?

DR CASTLEMAN: Yes. Those are the ones that frequently bleed.

DR JONES: Was there a large vessel in the middle of a fairly large ulcer?

DR CASTLEMAN: The ulcer was not large, it measured 1 cm in diameter and did have a protruding eroded vessel in its center. Apparently the patient must have bled before admission, the bleeding stopped when he came into the Emergency Ward but began again on the following day.

DR MARKS: Was it an acute ulcer?

DR CASTLEMAN: It was an acute erosion of an old ulcer. There was definite evidence of old ulceration.

DR JONES: There is one thing that may be of some importance. As Dr Marks pointed out, this patient was seventy-four years old and the story these people tell is frequently different from that of a younger person. It is not uncommon to have bleeding from an ulcer without pain at the time of hemorrhage, but it is not too common to have chronic ulcer and no symptoms whatever. Those in the older age group, however, often have no symptoms and may even perforate without pain. They do not perceive pain as readily as a younger person, and that may change the story a bit.

HIGH LIGHTS OF THE MEETING OF THE EXECUTIVE COMMITTEE OF THE COUNCIL

ONE could not have participated in the recent meetings of the Council of the Massachusetts Medical Society without having been impressed with how widespread the Society's activities have become. The vision created by such activities takes this organization out of its semicloistered past and places it squarely in the middle of an active and turbulent world.

The time consumed by the Council in the consideration of these necessary activities has caused many to believe that some change in its method of

procedure is called for. Certain steps in this direction have already been taken. The publication of the agenda in advance of the Council meeting is one of them. The formation of the Committee on Council Rules and the subsequent adoption of certain rules of procedure comprise another. It is quite likely that additional rules need adoption, — for example, limitation of the time of debate, — if the conduct of the business of the Society is to keep pace with the fast moving tempo of the times. Rules, however, that are not enforced and in whose enforcement the Council shows no interest will never solve the problem. Such rules are of importance only if they reflect the willingness of the Council to exercise this kind of self-discipline.

The annual meeting of the Council was not held this year because of the restrictions imposed by the ODT. In lieu of this meeting the Executive Committee of the Council met on May 23, 1945. The meeting was called to order at 10:30 a.m. and continued in session, except for a short recess for luncheon, until after 5:00 p.m.

The report of the Treasurer showed the excellent state of the Society's finances.

The report of the Subcommittee on Labor and Industry of the Committee on Public Relations spoke of the committee's conferences with labor and industry and of what it had learned of their respective points of view regarding the distribution of medical care. It emphasized the opportunities that such conferences give to publicize the Society's attempt along these lines through the aegis of the Blue Shield.

The Subcommittee on Public Information of the Committee on Public Relations strained hard at the traditional moorings of the Massachusetts Medical Society. Its report favored the Society's use of paid newspaper and magazine advertising as a means of getting over its messages to the public. That there has been considerable change in the thinking of the Council along these lines is evidenced by the fact that the subcommittee was directed to continue its study and by the further fact that a thousand dollars was placed at its disposal for the purposes of the study.

The supervision of the Medical Information Bureau was turned over to the Subcommittee on

Postgraduate Education of the Postwar Planning Committee

The report of the Committee on Legislation demonstrated that this committee has made full use of the Society's potentialities. The action of the Legislature on June 6, 1945, in referring to the next General Court a bill that would specifically exempt, until July, 1949, a substandard school from the provisions of the Medical Practice Act seems to bear this out. In this connection, however, it must be remembered that the so-called "Chiropractic Bill" is still before the Legislature. The Society owes much to the vigorous leadership of this committee.

The report of the Committee on Society Headquarters recognized the inadequacy of the space now allotted to the administrative activities of the Society. It offered certain solutions, and was authorized to pursue this subject along the lines recommended.

The Postwar Loan Fund was finally authorized, and an initial sum of \$25,000 from the Society's funds was set aside for this purpose. The administrative details have been placed in the hands of a new committee, which has already been appointed by the President.

The report of the Committee on Medical Education showed commendable activity. Under the G. I. Bill of Rights the veteran is entitled to certain opportunities to further his education. Regarding the educational opportunities that relate to the healing arts, there is grave danger that the veteran may spend his time and effort in a school that cannot adequately prepare him in the chosen field. The committee has offered advice in this regard to the Massachusetts Department of Education. The advice was gladly received, and assurance was given of its continued use. This department certifies to the Veterans Bureau the schools that are suitable for training under the bill.

Although the Committee on Rehabilitation offered no report, certain information came to the Executive Committee concerning its activities. The Massachusetts Department of Rehabilitation, as part of its program, is taking notice of those who are in what is termed "a state of static remediable disability." Briefly, this refers to the person

who, because of a disability that is static and remedial, cannot take his rightful place in the community. The department proposes to pay the expenses, both hospital and medical, of his rehabilitation. The person's inability to meet the expense involved must be shown, but indigence need not be proved. The Committee on Rehabilitation is at present working with the department on a fee schedule that will cover physicians' services under this heading.

The revival of the New England Medical Council, defunct since 1933, was the subject of a communication from the Rhode Island State Medical Society. The Executive Committee voted to participate.

The President spoke of a meeting that he had recently attended in Michigan. He said that the presidents of seventeen other state medical societies were present. He referred to a resolution that had been adopted at this meeting, part of which called for the creation of a planning committee in each of the states represented and in such other states as wished to participate. It would be the function of these committees to study problems of national interest. They severally would meet from time to time for exchange of views. In the thought behind this movement there was no intention to interfere in any way with the functions or prerogatives of the House of Delegates of the American Medical Association. It was hoped that this type of organization might be of help to the Council on Medical Service and Public Relations of the American Medical Association. The Executive Committee voted to participate in this matter and designated the Committee on Public Relations as the agency of the Society best suited to this purpose.

SECOND ANNUAL REPORT OF THE CHILDREN'S CENTER

A YEAR and a half ago, the *Journal* commented editorially on the most recent addition to Boston's community of medical institutions, the Children's Center in Roxbury, and reviewed briefly its activities and its accomplishments from its establishment in January, 1943.*

The Center has now published its second annual

*Editorial: The Children's Center. *New Eng. J. Med.* 229:732, 1943.

report, a sign that it has passed through its uncertain years of infancy and has emerged into its increasingly fruitful, if still somewhat youthful, period of maturing development. Interested friends and well-wishers can now view its aims and purposes with a better perspective, and no doubt its directors and staff will admit that they, too, can see more clearly the road that they are traveling.

The purpose of the Children's Center is an extremely fundamental one — to go back so far as possible toward the beginning of human behavior patterns, to attempt to analyze the cause of failure in adjustment and to set up machinery by which it can be corrected. According to the introductory words of the report, "the second year of the Children's Center has brought gratifying progress toward its goal as an institute where emotionally disturbed young children may be helped to lead happy and useful lives, and where a fuller understanding may be gained of the factors which make for harmony or disharmony in the development of the human personality."

That referring agencies and the community at large have come to an appreciation of the purposes of the institution is attested by the fact that, although fewer applications for enrollment have been made, the percentage of acceptances, owing to their suitability, has greatly increased.

An important and unique factor in the success of this organization is its employment of the nursery school as a means of studying and retraining the child, thus providing re-education of the emotionally disturbed subject in a group setting. Individual psychotherapy is started at the same time, and conferences with the parent complete the triad of therapeutic measures.

An institution such as this, if it is to achieve its highest degree of usefulness, must, in addition to therapy and research, assume the obligation of teaching. This the Children's Center has done by providing, during the past academic year, field work for two social workers, two students of psychiatric social work, eight nursery-school students and a psychiatric fellow assigned to the Judge Baker Guidance Center. Furthermore, nurses in training at the Boston City Hospital have come two at a time to assist in the nursery school, and members

of the staff have been utilized for lectures and seminars given to various groups in the community.

All in all, the Children's Center appears to be successfully and eminently fulfilling the aims that have been conceived by its sponsors, directors and staff.

MASSACHUSETTS MEDICAL SOCIETY

DEATH

McPHERSON — George E. McPherson, M.D., of Amherst, died June 16. He was in his sixty-ninth year.

Dr. McPherson received his degree from Baltimore Medical College in 1904, and became a staff member at the Carney Hospital, South Boston, in 1912. He left there to become neuropsychiatric specialist at the Sturdy Memorial Hospital in Attleboro and later became superintendent at the Foxboro State Hospital. He served for two years as assistant executive officer at the Boston Psychopathic Hospital and assistant superintendent at the Medfield State Hospital. He was superintendent at the Belchertown State School for twenty-one years before his retirement. He was a fellow of the American Medical Association.

His widow, a daughter, a son and five grandchildren survive.

Whooping cough	673	724	635

*Made reportable December 1943.

†Four year average.

COMMENT

Diphtheria recorded a welcome reduction of 10 cases from the previous month. Incidence is now only moderately high as compared to the seven-year median.

Meningococcal meningitis showed a slight lowering of its previous high level relative to the seven-year median. Case incidence for the month of May of last year was more than twice that for the present May and that for May, 1943, four times the present figure.

Mumps maintained its seasonal downward trend.

This is the first time that not a case of typhoid fever was reported in the month of May.

Pulmonary tuberculosis showed an increase and was moderately above the seven-year median. In part, this reflected the results of intensified case-finding programs, which will influence the figures for some time. The great increase in tuberculosis predicted as a result of the war has not materialized.

GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Anterior poliomyelitis was reported from Camp Myles Standish, 1, total, 1.

Diphtheria was reported from Arlington, 1, Boston, 5, Camp Edwards, 1, Camp Myles Standish, 1, Chelmsford, 1, Framingham, 1, Lawrence, 1, Melrose, 1, New Bedford, 1, Salem, 1, total, 14.

Dysentery, bacillary, was reported from Boston, 1, Holyoke, 1, Springfield, 1, Worcester (State Hospital), 16, total 19.

Encephalitis, infectious, was reported from Yarmouth, 1, total 1.

Malaria was reported from Boston, 1, Camp Edwards, 81, Cushing General Hospital, 3, Fort Devens, 44, Northampton (U S Veterans Hospital), 5, Waltham Regional Hospital, 11, Worcester, 1, total 146.

Meningitis, meningococcal was reported from Boston, 5, Brookline, 1, Cambridge, 1, Dartmouth, 1, Everett, 1, Haverhill, 1, Lowell, 1, Lynn, 1, New Bedford, 1, North Attleboro, 1, Quincy, 1, Seekonk, 1, Somerville, 1, Springfield, 1, West Bridgewater, 1, total, 19.

Meningitis, pneumococcal, was reported from Andover, 1, Boston, 1, Cambridge, 2, Northampton, 1, total, 5.

Meningitis, streptococcal, was reported from Arlington, 1, total, 1.

Meningitis, other forms, was reported from Boston, 1, Cambridge, 1, Norwood, 1, Worcester, 1, total 4.

Meningitis, undetermined, was reported from Worcester, 1, total, 1.

Salmonella infections were reported from Boston, 2, Newton, 1, total, 3.

Septic sore throat was reported from Boston, 2, Fort Devens, 1, Merrimac, 2, Somerville, 2, Williamstown, 2, Worcester, 1, total 10.

Trichinosis was reported from Boston, 1, Somerville, 1, Worcester, 1, total 3.

Undulant fever was reported from Paxton, 1, Pembroke, 1, total 2.

CONSULTATION CLINICS FOR CRIPPLED CHILDREN IN MASSACHUSETTS UNDER THE PROVISIONS OF THE SOCIAL SECURITY ACT

CLINIC	DATE	CLINIC CONSULTANT
Salem	July 2	Paul W. Hugenberger
Lowell	July 6	Albert H. Brewster

MISCELLANY

SOCIAL AND ENVIRONMENTAL FACTORS IN MEDICINE

The teaching of the social and environmental factors in medicine, as now carried on in medical schools in this country, is being studied by the Association of American Medical Colleges in co-operation with the American Association of Medical Social Workers. A grant to finance the study has been given by the Milbank Memorial Fund. A committee of twenty-five physicians and medical social workers who are engaged in this teaching has been formed to direct the study, under the name of the Joint Committee on the Teaching of the Social and Environmental Factors in Medicine. The co-chairmen are Dr. J. A. Curran, president of the Long Island

College of Medicine, and Miss Eleano. Cockerill, associate professor of social case work at the School of Applied Social Sciences, University of Pittsburgh. A centrally located project subcommittee has been set up under the chairmanship of Dr. J. E. Rhoads, assistant professor of surgical research and acting director of the Harrison Department of Surgical Research, University of Pennsylvania School of Medicine. The executive secretary of the study is Miss Harriett M. Bartlett, 49 Fruit Street, Boston 14.

It is the aim of the study to bring together and analyze the experience of a group of medical schools in introducing students to the social and environmental components in medicine. Visits to selected centers will be made by members of the committee. The study is expected to last through 1947, at the end of which time a report summarizing the findings will be prepared.

NOTE

The official corporate name of the Newton Hospital has been changed to the Newton-Wellesley Hospital, the necessary action having been taken by the members of the Corporation and approval thereof secured from the Commissioner of Corporations and Taxation.

BOOK REVIEW

Strophanthin. Clinical and experimental experiences of the past twenty-five years. By Bruno Kisch, M.D. 8°, cloth, 158 pp., with 24 illustrations. New York: Brooklyn Medical Press, 1944, \$4.00.

Kisch has done a useful service in summarizing the present status of the use of strophanthin and the history of its introduction in the therapy of heart failure. The small volume is well printed but is expensive.

There are seven chapters and a bibliography of thirty pages. In the preface, the author leaves out, in the opinion of the reviewer, the most important reason why Americans have not adopted strophanthin more generally and routinely, that reason being the excellent experience they have had with the intravenous use of digitalis preparations, which has so sufficed in emergency treatment that strophanthin has been simply an alternative. Kisch speaks of the experience in the United States as being characteristic of that throughout the Western Hemisphere, but in Latin America strophanthin has been in regular use.

The historical introduction is extremely interesting and is worth while reading in toto. The clinical applications of the drug are clearly presented in Chapter 5.

This book can be recommended to all those interested in the treatment of heart disease.

NOTICES

SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING THURSDAY, JULY 12

FRIDAY, JULY 13

*9:00-10:00 a.m. Medical clinic. Isolation Amphitheater. Children's Hospital.

10:30 a.m. Introduction to Dermatology. Dr. John G. Downing (Postgraduate clinic in dermatology and syphilology). Amphitheater. Mallory Building. Boston City Hospital.

12:00 m-1:00 p.m. Clinicopathological conference (Boston Floating Hospital). Joseph H. Pratt. Diagnostic Hospital.

MONDAY, JULY 16

*12:00 m-1:00 p.m. Clinicopathological conference. Peter Best. Brigham Hospital.

TUESDAY, JULY 17

*9:00-10:00 a.m. Medical clinic. Infants Hospital.

*12:15-1:15 p.m. Clinicoradiological conference. Peter Best. Brigham Hospital.

WEDNESDAY, JULY 18

*12:00 m. Clinicopathological conference. Children's Hospital.

*Open to the medical profession.

THE HISTORY OF MIDDLESEX NORTH DISTRICT MEDICAL SOCIETY 1844-1944*

ARCHIBALD R. GARDNER, M.D.

LOWELL, MASSACHUSETTS

CONDENSATION of time and space is one of the important characteristics of this civilization, and, as this is the centennial anniversary of our local society, an attempt will be made to condense one hundred years of its growth within the short time allotted. The great historian Livy complained of the scant records of the early history of Rome, but that was not my difficulty in this case. My problem was to select from the abundance of records some topics that might be of interest to you. Most of us like people better than dates, which is indeed an essential trait of physicians. There are, however, a few dates and associations of our early society's chronicles that will give a historical perspective.

No discourse pertaining to the history of the Middlesex North District Medical Society should be given without a clear statement of its relation to its parent, the Massachusetts Medical Society. The latter, founded one hundred and sixty-three years ago, is the oldest medical society in the United States with a record of uninterrupted activities from its founding to the present time.

In the Charter Act of the Legislature of 1781, there was no provision for the forming of local or district medical societies, integral parts of the parent society, in the different sections of the Commonwealth. These district or county medical societies have since become prominent features of all state medical societies, their boundaries usually conforming to counties.

In 1829 the first medical association in Middlesex County was formed. The meeting was held in Lexington. Dr. Josiah Bartlett, of Chelmsford, was chosen president, and Dr. F. S. Hurd secretary. The physicians of Lowell who were present at that meeting were Drs. Green, Huntington, Crosby and Bartlett. Unfortunately, the records of this association have been lost.

In 1833 the members were forced to dissolve their association on account of the time and expense involved in going by stage to and from their then distant places of meeting, and for several years there

was no formal organization or association of physicians in this vicinity.

The town of Lowell was rapidly growing, following the building of its fine system of canals, which so greatly contributed to the ever increasing textile industry. By 1836 the town had become a city. Keeping pace with this growth, the number of physicians was increasing, and the old association had awakened a spirit, for in man there is an instinct to band with others for mutual benefit, not alone in matters of government, but also for the help derived from aggregate knowledge and experience, this being especially true regarding the followers of our calling. So it was but natural that another medical association should be formed.

In 1839, a special meeting of Lowell physicians was held at the office of Dr. J. D. Pillsbury to organize a society for mutual improvement, at which time the Lowell Medical Association was formed. The following physicians were present: Elisha Bartlett, John C. Dalton, James W. Ford, J. W. Graves, William Grey, J. P. Jewett, Gilman Kimball, George Mansfield, Daniel Mowe, Hiram Parker, Otis Perham, Harlin Pillsbury, J. D. Pillsbury, J. W. Scribner, Benjamin Skelton and Daniel Wells. This voluntary association of high character continued to grow in numbers and increase in interest until at the end of five years a request was made by some members of the Massachusetts Medical Society, resident in this vicinity, for the establishment of a district medical society.

The committee reported at the October meeting in that year that they had drawn up a petition for such a society, which had been signed by twenty-three out of twenty-seven fellows residing in the proposed district, and accordingly recommended that a charter be granted. This was passed promptly by a unanimous vote. The petition follows:

The undersigned members of the Massachusetts Medical Society, resident in the northerly section of the County of Middlesex, believe that the establishment of a district medical society within its limits embracing the following towns, namely: Lowell, Billerica, Ashby, Townsend, Pepperell, Dunstable, Groton, Shirley, Tyngsboro, Chelmsford, Carlisle, Littleton, Dracut, Tewksbury, Concord, and Acton (the meetings of which shall be holden in the City

*An address delivered at the Centennial Observance of the Middlesex North District Society, December 6, 1944.

of Lowell) would be of great utility. Being desirous of enjoying the advantages and privileges of such an institution, we do hereby pledge ourselves (should a petition for a charter to that effect already in the hands of the Councillors be granted) to become active members of the same, by attending its meetings and otherwise promoting the interest as opportunity may occur.

This charter was received November 2, 1844, and the society was known as the Middlesex District Medical Society.

In 1850 a slight change was made. Middlesex County was divided into three districts—east, north and south. This city and eighteen neighboring towns were included in the North District, and the name of the society was changed to the Middlesex North District Medical Society, which it has retained ever since. The caliber of the members in the society of that period can be judged from the fact that in their desire to perpetuate their knowledge of medical science Dr. Elisha Huntington petitioned the Legislature for a charter to establish a medical school in Lowell.

In the formation of medical societies at that time, the objects were to combine physicians and surgeons duly qualified to serve the public as such, to point out the education to be pursued by those who should be desirous of entering our profession, to examine persons who had pursued this course and to give licenses to such as should be found qualified to engage in practice.

The medical societies in those years were the only organizations that controlled the standards of medical practice. It was not until 1894 that Massachusetts joined the majority of the other states of the Union in adopting a medical practice act, thereby establishing the Board of Registration in Medicine. This act, indeed, proved most undesirable, since it allowed incompetent doctors to be registered in the Commonwealth, but after years of constant efforts on the part of the medical societies, the Legislature was lately induced to correct conditions by passing a satisfactory bill. One has only to read the various advertisements in the magazines and journals of those days to note the extent of quackery and charlatanism. It has been stated that with the promotion of the local district medical society, the public in this locality had its first effective protection from those unscrupulous and dishonest medical pretenders.

The meetings of the earlier associations were held at the various members' homes for social converse, literary improvement and the exchange of fraternal courtesies. We later learn that meetings of the Middlesex North District Medical Society were held for thirty years in the Natural History Rooms of the Mechanics Building in Dutton Street, where the Genoa Club is now located. The first meetings held were in the nature of clinics where patients were examined free by three or more selected members. This practice was soon discontinued, and case reports were discussed, often with autopsy findings. Later, scientific papers were presented by members

who were selected alphabetically. During the last twenty-five years the papers have usually been given by members of the profession from the large centers and teaching institutions.

It is interesting to note the subjects of some of the addresses given in those early days at the meetings. For instance, Dr. John C. Dalton spoke on "Certainty in Medicine." One wonders just how much closer we have approached to "certainty" since that time. Dr. Zadok Howe, a family physician of Billerica, spoke of "Fear in Connection with Medicine." Without doubt this was the first psychiatric address ever given in this county. Fortunately, perhaps, he did not have the Freudian advantages of the modern-day specialist. "Cholera" was the subject of an address given by Dr. J. O. Green at a time when the disease was prevalent in the county. He also included in his paper a report drawn up by him as a member of a delegation consisting of himself, Dr. Bartlett and Dr. Huntington. These men had been appointed to investigate and report the nature, remedies and preventives of cholera, and were sent to New York by the select men of Lowell, one of whom was Dr. Josiah Crosby. This is early evidence of the importance of our society in its constant attention to affairs concerning the general public health.

The reports of the earlier meetings show that they were not so harmonious as those we are accustomed to attend. In fact, if it had not been for our legal connection with the state society, the district association would have been abandoned, since the dissensions among members were often long and loud. The subject of the controversies was usually based on questions of ethics and methods of practice.

There were periods when the meetings were not well attended. In 1879, it was voted that the meetings be followed by a dinner and the attendance was greatly increased with an interest that has never since lessened. The oft-repeated expression, "The way to a man's heart is by his stomach," is the keynote to the revival of this society.

Some of the most heated and lively discussions occurred at times when the community was in the throes of epidemics of scarlet fever, diphtheria, typhoid fever, meningitis, smallpox and cholera. The mere naming of this list of diseases, which were most prevalent in epidemic form during the early period of this society, impresses on one the tremendous advances that have been made in medicine since that time.

In those days, as now, the physicians and surgeons gave generously of their time and skill to charity. Of course they had a fee table, and it may be interesting to note some of the charges.

For a visit within one mile	\$ 75
Each additional mile	25
Visit in night (night is understood as beginning at 10 p. m. and ending at sunrise)	1 00
Advice in ordinary office cases	25
Advice in ordinary office cases and medicine	50

Small dressings at office	50
Extracting tooth	50
Each additional tooth	25
Obstetrical case	5 00
Amputation of fingers and toes	1 00 each
Reducing fracture of large limbs	5 00

Obviously there was no inflation in those days

It was stated in an editorial of the *Boston Medical and Surgical Journal* in 1847 that Lowell in 1846 contained 28,841 inhabitants. In that year there were 690 deaths, "pulmonary consumption," as everywhere in New England, swept off the greatest number, and scarlet fever was the next active agent in destroying human life. In the field of surgery, on the other hand, in another two years the world will be celebrating the hundredth anniversary of the greatest boon to modern surgery, namely, ether. It was only two years after the founding of our society that, within twenty-five miles from here, at the Massachusetts General Hospital, occurred the first public demonstration of the anesthetic properties of ether.

With the banishing of pain in operative cases there was still the specter of infection remaining, as in erysipelas, pyemia, septicemia, and gangrene, from which no surgical patient was safe. The work of Pasteur demonstrated that organisms and bacteria, airborne and otherwise, were the source of wound infections, following which Lister attempted to prevent infection by antiseptic methods. It was later in the eighties that the modern aseptic technic was developed. All this time members of our society were at work here in Lowell, first at the Corporation Hospital, where Kimball did his original and pioneer work under antiseptic methods, and later at St. John's Hospital, where aseptic technics were introduced and developed by some of our keen and progressive members.

Our fellows were well aware of the newer discoveries by engineers and scientists in public-health matters. Several members were the instigators and organizers of the Massachusetts Public Health Association.

In the early days of our society, the practice of medicine was more of an art than a science. It was largely carried on in patients' homes or doctors' offices. The doctors early learned that the best work could be done in hospitals, of which we have three—the old Corporation Hospital, organized in 1839 and now known as St. Joseph's Hospital, St. John's Hospital, founded in 1865, and the Lowell General Hospital, founded thirty years later.

The latter part of the century had become an age of science. Such diseases as tuberculosis, diabetes, pernicious anemia and some cases of cancer were no longer necessarily mortal diseases.

Within a few months following the publishing of the original paper describing the discovery of x-rays, forty-nine years ago, an x-ray picture of a coin and hairpin was taken through a book with an apparatus set up at the Lowell High School by Cyrus W. Irish and Arthur Gage. This is an example of the

alertness of our members to the importance of new scientific discoveries and their possible clinical application.

In the lifetime of this district society there has been more advance and progress in medical science than in all the centuries that preceded. One wonders what science will offer in the future. I hope, however, that a hundred years from tonight the menu will not consist of a couple of capsules and an intravenous infusion administered by a white-garbed nurse to each as he enters the banquet hall.

As I stated earlier that we like people better than dates let us turn to some interesting and important personalities outstanding in the history of our society.

Among the men who led in conducting the affairs of the society in those early years are the following first officers elected: Dr. Nehemiah Cutter, of Pepperell, president, Dr. Elisha Huntington, of Lowell, vice-president, Dr. John D. Pillsbury, of Lowell, secretary, Dr. J. P. Jewett, of Lowell, treasurer, Dr. J. W. Scribner, of Lowell, librarian, and Drs. Augustus Pierce, of Tyngsboro, Elisha Huntington, of Lowell, and Harlin Pillsbury, of Lowell, members of the Standing Committee.

Dr. David N. Patterson wrote necrologies of the physicians of Lowell and vicinity from the year 1826 to 1898, and to him must be given credit for recording much of interest in connection with our society, including the sketches of the lives of many of the more prominent members.

There have been many distinguished fellows of the Middlesex North District Society, and it would be a great injustice to the memory of those fine and able men if some recognition were not given to their labors at this centennial celebration.

Among the many physicians who have practiced in this city is one who by his original views and fearless conduct was far in advance of his times as a medical practitioner and writer. Dr. Elisha Bartlett was a highly accomplished scholar and physician. He was an extremely popular medical teacher and a ready lecturer. He also attained great eminence as an author, and his published books and pamphlets, both professional and miscellaneous, are numerous. He held various professorships in the Berkshire Medical Institution at Pittsfield, the Medical Department at Dartmouth College, Louisville University and the medical college at Woodstock, Vermont.

It is an honor to the medical profession that one from its ranks was chosen to be the first mayor of this city. It was a mark of special distinction that this responsible trust should have been bestowed on Dr. Bartlett when only thirty-two years of age. Dr. Oliver Wendell Holmes, a lifelong and intimate friend of Dr. Bartlett, when speaking of his death remarked that his loss was a national calamity.

In 1824, two years before the incorporation of the town of Lowell, there came into this place a young

man possessing unusually promising traits of character. These and other excellent qualities were united in the person of Dr Elisha Huntington. He was an able physician of rare culture and scholarly attainments. As a family physician he enjoyed the confidence and high regard of a large number of families in this community, who retained his services as long as he lived. Charity to the poor was one of his marked characteristics. Dr Huntington, in presiding at the head of the municipal government, finished a career that has never been excelled in local history. In 1856 he entered for the seventh time on the duties of mayor. So long as the fame of this city shall survive, the public services of Dr Huntington will live on Lowell's records, and his name will occupy a prominent place in its history.

Prominent among the early physicians stands the name of John C Dalton. Dr Dalton was an ardent lover of his profession, and gleaned those acquisitions that enabled him to take high rank not only with his local medical associates but among the leading physicians of the Commonwealth. The entrance of a young physician into professional life in those days was somewhat different from the usual custom of later years. In some respects it was not unlike that of a minister receiving a call to serve a parish. Dr Dalton virtually received a call from the people of Chelmsford, and it was extended in the following manner. In 1818 Dr Wyman, who was then practicing at Chelmsford but had received an appointment as superintendent of McLean Asylum, was requested by the citizens of the town to appoint a successor. On his recommendation, Dr Dalton, then in his twenty-third year, began his practice.

An amusing incident, as related by Dr Dalton, occurred on his first coming to Chelmsford, the mother town of Lowell. Dr Wyman took him around to different parts of the town and introduced him to the leading families, speaking a good word in his behalf, for he looked very youthful as compared with Dr Wyman. In calling on one of the principal families, its head, a man remarkable for age and wisdom, after making a survey of the "young doctor" remarked that a physician would have to fill more than one graveyard before he had a chance to experiment on him. Notwithstanding the shock this remark made on the young Dr Dalton at the time, this family became one of his best patrons.

Very few men have had the distinction of having four eminent sons as did Dr Dalton. Two of them became noted physicians, and through the generosity and interest of one of the other sons a substantial sum, long known as the Dalton Scholarship Fund, was established for medical research at the Massachusetts General Hospital.

A bold and daring pioneer surgeon of this city who, through his explorations in uncharted surgical fields, before the discoveries of Louis Pasteur and Lord Lister, contributed much to medical science for the relief of suffering humanity was Dr Gilman

Kimball. When the Lowell Corporation Hospital was established, Dr Kimball was elected physician-in-charge. He was retained in this position for twenty-six years.

Dr Kimball was one of the first in the practice of ovariectomy in this country. There is no other operation known to medical science that early met with such decided opposition on every hand as did this branch of operative surgery. The mortality was large. At that time the whole number of surgeons in this country who had ever performed this operation was less than ten. Before Dr Kimball's death he performed ovariectomy in 300 cases. According to Dr Howard Kelly, of Johns Hopkins, Dr Kimball has the distinction of being the first surgeon to perform successfully the removal of the whole of the uterus based on a correctly established diagnosis. He performed this operation in 12 cases, with 6 recoveries. In 1842, he was elected to succeed the brilliant Dr Willard Parker, of New York City, — one of Chelmsford's gifted sons, — as professor of surgery in the medical college at Woodstock, Vermont, and in the following year he was chosen to fill a similar position in the Berkshire Medical Institution at Pittsfield, Massachusetts. His name will pass into history as one of the foremost surgeons of this country.

At this time, mention should be made of some of the leading surgeons and physicians of the latter part of the century just closed, who can still be remembered by many. One whose name is familiar to all is Dr Moses Greeley Parker. Through his generosity he made it possible for the people of this district to enjoy the best in music, literature and art, as well as lectures on travel, health and hygiene. As a benefactor to the society he left a fund to provide dinners at the meetings similar to the well known Cotting Lunch Fund of the Massachusetts Medical Society. Others are Dr John C. Irish, a leading and skillful surgeon, and his two apt and able pupils Dr Robert E. Bell and Dr Joe V. Meigs, who were eminently successful surgeons. Dr Francis C. Plunkett was a beloved family physician and an original staff member at St. John's Hospital, where he served actively and ably for many years. Dr George H. Pillsbury was a cultured medical gentleman, whose father, Dr Harlin Pillsbury, was one of the charter members of this society.

One of the society's most energetic members during the last years of the century, who through his clear vision and forcible speaking was able to unify the profession in matters calling for firm and advanced action, was Dr J. Arthur Gage. In 1930 this society tendered to Dr Gage on his retirement a farewell banquet in testimony to his great worth and value to the community that he had served so well, for he was an acknowledged leader.

Finally, it may be said that the lives of these men who acquired, both in medicine and in other fields of civic endeavors, honorable distinction

among their contemporaries stand out as steps of progress in the growth of our society. Others equally deserving could be mentioned if time permitted.

The society has always had its quota of physicians in the Medical Corps of the United States Army and Navy. Not only in the Civil War and World War I have the doctors of Middlesex North District Medical Society taken an active part, but in the midst of World War II this society is well represented on all war fronts. We are proud of their work and the spirit that carries them on. If it were possible they would be here with us tonight. Since this cannot be, our earnest wish is that our prayers will be answered and that these young men may come

back to us safely. On their return after this conflict may they find that our association is appreciative in full measure of their unselfish efforts and the un-failing sacrifices that they have made. Furthermore, not only does the society know their true worth, but the wounded and sick soldiers know its members' skill. They also have felt the warmth of heart and sincerity of our profession.

When, in the course of time, another century of this society's existence shall have passed into history, the men then taking our places, even with their advances in the knowledge of medical science, can surely take an honest pride in the efforts, experiences and accomplishments of the physicians of the century just closed.

EARLY RISING AFTER SURGICAL OPERATIONS

JOSEPH ASHKINS, M D *

MILFORD, MASSACHUSETTS

THE question of when a patient should arise following an operation is one concerning which there has for many years been considerable divergence of opinion. There has been an increasing tendency to get patients out of bed early, but few surgeons, particularly those of this country, have advocated that patients walk from the operating table or become ambulatory twenty-four to forty-eight hours postoperatively. Surgeons who have adopted this routine claim that all postoperative complications such as pneumonia, wound infection, thrombosis and embolism are less frequent than they are in the mobilized patient. Shortly after the turn of the century, largely owing to the work of Ries,¹ of Chicago, and Kummell,² of Hamburg, early post-operative rising had many advocates, but this routine gradually fell into disrepute until recently.

In 1937, Kimbarovskiy³ reported on 551 cases. Of 71 patients operated on for hernia of the linea alba, all walked from the operating table and 96 per cent were discharged not later than the seventh day after operation. Of 124 patients with inguinal or femoral hernias, 67 per cent walked from the operating table and 29 per cent arose on the following day, 94 per cent were discharged not later than the eighth day after operation. Of 210 patients with chronic appendicitis, 84 per cent arose on the following day, 79 per cent were discharged not later than the seventh day after operation. Finally, of 146 patients who had a gastric resection for ulcer, 63 per cent arose on the second hospital day and 26 per cent on the third, 42 per cent were discharged not later than the ninth day after operation. Kimbarovskiy is convinced that the incidence of post-

operative pneumonia, wound infection, thrombosis and embolism is lowered and that the incidence of hematoma and wound disruption is not increased in such patients.

In a subsequent paper he⁴ states that in a series of 1600 patients handled in this manner, the incidence of thrombosis and embolism was only 0.2 per cent. In the same paper he reports concerning experiments with 30 dogs. In all, the abdomen was incised in the midline and the stomach was incised. Half were kept recumbent and half were allowed complete movement, equal numbers of each group being killed on the fifth, seventh and ninth days. The scars in the stomach and abdominal wall were examined microscopically, those of the stomach were identical in both groups, whereas those of the abdominal wall showed much better healing in the active group than in the immobilized group.

In 1940, Niedeggen⁵ published an account of 1646 patients who were induced to leave their beds within twenty-four hours of operation if they had been ambulatory before it was performed and if they did not have a high fever. On the morning after operation, a nurse raised the upper part of the body from the pillow and another swung the legs over the edge of the bed. The patient was assisted to his feet and walked about the room for several minutes, being supported on both sides, and then was helped back to bed. This was repeated six hours later. On the second day, most of the patients were attended with little difficulty and many of them had their meals at a table. By the third or fourth day, little was required in the way of special care, and on the fifth or sixth day, it was not unusual to see patients walking in the garden or making themselves useful about the hospital. If there was marked exaggeration of

*Surgeon, Milford Hospital

wound pain, it was almost always due to an incorrect technic in getting up or to dressings so applied that pressure or traction resulted. In the entire series the incidence of thrombosis and phlebitis was 0.5 per cent, and 0.35 per cent of these patients had evidence of embolism. The operative mortality was 0.18 per cent, and not a single case was lost because of a pulmonary infarction. The types of operation are not given, but it is stated that of 51 patients who underwent gastric operations only 1 had a postoperative bronchitis and none had a subsequent pneumonia.

In 1938, Campeanu⁶ reported the end results in 1300 cases in which the patients either walked away from the operating table, if local anesthesia had been used, or arose from their beds as soon as paralysis had disappeared, if spinal anesthesia had been employed. The most frequent operations were as follows: appendectomy, 682 cases, phrenectomy, 165 cases, herniotomy, 126 cases, gastroenterostomy, 42 cases, gastric resection, 33 cases, resection of adhesions, 32 cases, and cholecystectomy, 28 cases. The operative mortality was 0.23 per cent, and not a single patient had a complication that could be attributed to early rising. Certain patients who had had an appendectomy or herniotomy left the hospital on the day of operation, and the majority had left by the third or fourth day, returning on the seventh day to have the stitches removed.

In this country, Leithauser and Bergo,⁷ in 1941, reported 436 cases in which the patients got out of bed soon after operation and were permitted to be ambulatory. The majority (370) of these patients suffered from acute or chronic appendicitis without evidence of spreading or generalized peritonitis. In the remaining patients the three most frequent operations were cholecystectomy (18 cases), herniorrhaphy (9 cases), hysterectomy (7 cases) and other pelvic procedures (6 cases). In the cases of appendectomy, the average number of days of confinement was 1.5 days and the average hospital stay 2.3 days. For the other cases, the figures were 1.9 days and 8.9 days, respectively, and the patients who were active on the first day had the most favorable convalescences. There was a single fatality due to a massive hemorrhage from jejunal ulcers, on the seventh postoperative day. Otherwise, there were no complications such as wound dehiscence, hernia, pneumonia and thrombophlebitis. These authors believe that early rising and graduated ambulatory activity increase the rate and depth of breathing and the tone and use of skeletal muscles, thus improving the circulation in the pulmonary, systemic portal and lymphatic systems, and that they probably promote the return of normal function of the vital organs and aid elimination through the kidneys.

Charbonnier⁸ starts his patients with deep breathing exercises and movements of arms and legs in bed during the period before rising, beginning as

soon as the patient has come out from the narcosis. His patients are never allowed to rise before the third postoperative day and are usually allowed to do so on the fourth postoperative day. In some cases they are kept in bed until the fifth day. In a series of 408 patients who underwent laparotomy there were only 17 who had postoperative complications, practically all these complications were minor, and none could be attributed to early rising. There was no case of evisceration or of pulmonary embolism, and there were no deaths.

Harild⁹ is opposed to early rising after laparotomy, chiefly because of reduction of the minute volume of the blood in connection with operation. In support of his position, he has made a study of the minute volume in patients who have undergone laparotomy for one of several conditions and in those on whom extra-abdominal operations have been performed. The types of laparotomy represented are appendectomy, laparotomy with ventrosuspension of the uterus, colostomy, exploratory choledochotomy and ventral herniotomy. Two extra-abdominal operations represented are radical extirpation of the breast and arthrotomy of the knee for a lesion of the meniscus. The minute volume was reduced after operation by 30 to 35 per cent, even in cases in which there were no clinical signs of circulatory disturbance. In cases with primary shock, the decrease was even more marked. In most of his cases there was little or no change in the minute volume on the first day after operation, the most marked changes occurring two or three days after it. He also notes that no clinical signs of cardiac deficiency were determinable, indicating that the cause of the changes in minute volume must be in the periphery. On the basis of these findings, Harild concludes that even though operation induces an increase of oxygen consumption there is a reduced minute volume, and that the increased need of the tissues for oxygen must be satisfied by way of an increased discharge of oxygen from the blood. On the basis of these findings he believes that it does not seem justifiable to permit patients to leave their beds after laparotomy, at a time when there is partial circulatory insufficiency.

Lindhart¹⁰ and other investigators have found that the transition from the supine to the sitting or standing position induces a reduction of the cardiac minute volume, and the experiments of Asmussen, Hohwu, Christensen and Nielsen¹¹ published in 1939, show that the circulation in the passive standing position must be looked on as actually insufficient. In this position, a considerable amount of blood, up to 500 cc., accumulates in the lower extremities. They believe that patients should lie abed until the circulatory deficiency has run its course, which requires from five to ten days and sometimes longer, depending on the gravity of the operation and possibly the type of anesthesia. Since a similar study was not conducted on those who arose early,

these findings can only be properly interpreted as showing what happens in the quiescent postoperative patient

Lerthausen,¹² in studying the vital capacity of 202 patients subjected to early rising, made readings each day in the lying, sitting and standing positions before and after surgical procedures on the abdomen. After early rising, the vital capacity returned to normal in half the prescribed period, convalescence closely followed the improvement in vital capacity. He believes that coughing exercises in the standing position are specific therapy for the rales and possible mucous plugs that may be present following operation.

In a review of the literature, Newburger¹³ notes the unfortunate experiences with early postoperative activity when coarse suture material and running stitches were used in closing the abdomen, many case histories ended with the notation, "On the tenth day they returned to the hospital with their guts in a napkin."

* * *

The patients who occasionally became ambulatory, and even violent, immediately after operative procedures as a result of accident or intercurrent disease and suffered no ill effects stimulated my interest in the possible advantages of early rising.

It was decided to allow young patients who were in good physical condition and who had undergone simple appendectomy to leave their beds as soon as they felt able. This usually occurred on the third or fourth day after operation. After a few months' experience, this same type of patient was urged to arise even earlier. Most were apprehensive and had to be assisted and encouraged, and it was with real trepidation that they took their first steps. These patients were not premedicated before becoming ambulatory, nor were they given lengthy encouragement. The nurses merely entered the room and requested the patient to rise and offered their assistance. Those who objected, a small percentage, were not forced to rise, but were encouraged again the next day and told that it was better for them to be out of bed early. Once up, they seemed particularly pleased in their ability to get along, and it was not difficult to keep them ambulatory. They were allowed to stay up for half an hour in the morning and half an hour in the afternoon. The period was lengthened each day, until on the fourth day the patient was in bed for only a short period in the morning and another in the afternoon. Emphasis was placed on the importance of walking. The patients were not merely moved from their beds and allowed to sit in chairs.

During the first day, the patient was usually rigid and apprehensive about moving and did not enjoy the procedure. On the second day, however, there was evidence of increased ability to move around.

By the fourth day the patients walked with comparative ease and could be found reading, lounging about or taking short walks without hesitation. Occasionally they reached this stage on the third postoperative day.

This method of treatment was gradually extended to include most postoperative patients except those too ill as a result of severe infection, previous disability or unusually severe postoperative reactions.

In patients subjected to more extensive procedures, such as cholecystectomy and hysterectomy, the routine was modified and they were allowed out of bed for ten minutes on the morning of the first postoperative day and again in the afternoon. They were occasionally given an opiate before rising. It was not until the third or fourth day that they stayed up for an hour at a time. Of the latter group, 20 per cent were unwilling to leave their beds until the second or third day.

The operative wounds in these cases were closed in a variety of ways. In all of them tissues were accurately approximated and bleeding points ligated. For a few years, silk was used to repair the fascia. At present, silk and fascia are being utilized in the repair of hernias, and other abdominal incisions are routinely closed with continuous No 0 chromic catgut to the peritoneum, interrupted No 1 chromic catgut to the fascia, No 000 chromic catgut to the subcutaneous tissue and black silk to the skin. The suture material used for vaginal plastics is No 0 or 1 chromic catgut. In upper abdominal longitudinal incisions, after suturing the peritoneum in the usual fashion, the rectus muscle is retracted. Almost invariably the transversalis fascia is found to be gaping in the superior half of the incision. It is impossible in most cases to close the peritoneum and transversalis fascia accurately with a single row of sutures, and many postoperative hernias may arise from failure to recognize this fact. In one follow-up of 393 patients operated on for gall-bladder disease, 12.9 per cent developed incisional hernias.¹⁴

In the present series of 823 patients who were out of bed on the first to third postoperative day (Table 1), there were no serious complications due to their early mobility.

These patients are instructed to return to the office for their first checkup in four to six weeks after operation. At the end of three months, another examination is made. If they are normal at that time, they are dismissed but are told to return if anything unusual occurs. Since many of these patients are from surrounding towns, the referring physicians usually make the succeeding examinations.

The following four complications have occurred. One patient, on whom a cholecystectomy was done, appeared normal at the first examination but later his physician stated that the operative wound was bulging and instructed him to wear a belt. Another patient, operated on for a recurrent inguinal hernia,

developed a thin area in the upper third of the operative wound six months after leaving the hospital. Protrusion does not exist at present, but it seems likely he will have a recurrence. A pulmonary infarct into the lower left lobe occurred in an obese male on the seventh day after he had been operated on for a gangrenous appendix. Recovery was complete. The fourth patient, admitted with a ruptured

ate oozing from the gall-bladder bed, it subsided promptly. Five grams of sulfanilamide powder was scattered widely throughout the operative area and a drain was inserted to the foramen of Winslow. The peritoneum was closed by continuous No. 0 chromic catgut, as was the transversalis in the upper portion of the wound. Three silk stay sutures were inserted, the fascia was closed by interrupted No. 1 chromic catgut, and black silk was used for the skin. The operation began at 12:45 a.m. and was completed at 1:20 a.m. The patient left the table in good condition.

When seen the following morning the patient appeared

TABLE 1 *Types of Operation in Patients Submitted to Early Rising*

TYPE OF OPERATION	YEAR								TOTAL No OF CASES
	1937	1938	1939	1940	1941	1942	1943	1944

ectopic pregnancy, ran an uneventful course until the eighth postoperative day, when she began to complain of pain in the calf of the right leg. Local tenderness, swelling and a positive Homans's sign were present. The thrombophlebitis remained localized, although slight swelling of the ankle persisted six months later.

All these patients were out of bed within twenty-four hours.

CASE REPORTS

CASE 1. J. C. (47706), a 72-year-old man, was admitted to the Milford Hospital on January 21, 1944, with a history of acute upper abdominal pain starting 36 hours previously. He was seen by his physician, who gave him 16 mg. of morphine, which brought partial relief. The following morning he was having chills and vomited repeatedly. He was again given morphine and experienced some relief. During the day he became progressively worse and was admitted to the hospital that evening.

On examination he appeared ill and uncomfortable. The temperature was 100.2°F, the pulse 94, the respirations 28, the blood pressure 140/76, and the white-cell count 21,400. The heart sounds were of good quality, with an occasional extrasystole. The chest was hyper-resonant, with many dry rales throughout both lungs. There were spasm and rigidity in the right upper quadrant of the abdomen, with maximum tenderness at a point 4 cm. lateral and somewhat superior to the umbilicus.

The diagnosis of an acutely inflamed gall bladder was made. The patient was given 5 per cent glucose in normal saline solution intravenously. After receiving 1500 cc., he was taken to the operating room with the drip still running at a rate of 60 drops a minute. Under nitrous oxide, oxygen and ether, a right upper rectus muscle-splitting incision was made. When the abdomen was opened, a swollen, tense, thick-walled gall bladder adherent to surrounding structures was found. It was freed by sharp and blunt dissection and walled off. An incision was made 1 cm. from the liver edge on the anterior surface of the gall bladder. It was deepened until a line of cleavage was made out, and the dissection was carried downward on the medial and lateral surfaces until the gastro-hepatic omentum was reached. This was carefully dissected, exposing the cystic duct and artery. They were doubly ligated and the gall bladder was removed. There was moder-

cyanotic. The respirations were audible outside the room. There were many moist rales throughout both lungs. A diagnosis of so-called "massive collapse" was made. The patient was placed on his feet, instructed to cough, walked a few steps and returned to bed. The cyanosis disappeared and the patient breathed comfortably, with but a few moist rales remaining. From then on, the postoperative course was uneventful. He was out of bed and walking each morning and afternoon. On the 4th postoperative day his general condition was good and he was eating well. He was discharged on the 6th day. At the last postoperative checkup, made on June 15, the operative wound was firm and nontender and gave no evidence of hernia.

CASE 2. H. W. (46869) a 47-year-old, obese woman, was admitted on September 14, 1944, with a history of having been under treatment for the last 2 years for menopausal symptoms. Five weeks previously, she began to bleed vaginally. One week before admission her physician examined her, stated that she had a fibroid uterus, and advised operation.

The general physical examination was essentially negative. On bimanual examination, the fundus was palpable 2 finger breadths above the symphysis. It was smoothly irregular, slightly tender and movable and filled both vaults. The cervix was hard and smooth but not otherwise remarkable.

On September 16, under nitrous oxide, oxygen and ether, a supravaginal hysterectomy was done after the manner of Curtis.¹⁵ During the first 24 hours the patient received 1000 cc. of 5 per cent glucose in normal saline solution and 2000 cc. of 5 per cent glucose in distilled water. She appeared comfortable on the morning after the operation. She was given 16 mg. of morphine and half an hour later, with one nurse lifting her feet and another supporting her shoulders, she was placed in a sitting position on the side of the bed. After a short interval, she was helped to step to the floor and was assisted in walking about the room. She sat in a chair for 10 minutes, walked back and was helped into bed. This process was repeated twice a day. On the 2nd and 3rd postoperative days she had a few gas pains with no visible distention. By the 5th day, with a nurse lending slight support, she was walking with assurance and appeared quite comfortable. She was discharged on September 25 with the wound healing by first intention and with no evidence of infection.

Her physician did the postoperative checkups and reported that she had had an uneventful convalescence.

CASE 3. M. N. (47867), a 26-year-old woman, was admitted on February 17, 1944, at term and in active labor. The head was not engaged. She was given a test of labor lasting

for 14 hours, but the head still failed to engage. She was then moved to the operating room for cesarean section.

Under nitrous oxide, oxygen and ether, a low midline incision was made. The peritoneal reflexion of the bladder was turned downward, and retractors were put in place. A transverse incision was made through the lower uterine segment. Unusually severe bleeding occurred from the uterine walls and was controlled by clamps. A living male child was extracted and 0.2 cc of Pituitrin was given intravenously. When the uterus began to contract, the placenta was removed. The incision in the uterus was closed by an inner layer of No. 1 chromic catgut sutures and an outer layer of interrupted sutures. Peritoneal reflexion was restored to cover the suture line. The pelvis was wiped out and the abdomen closed in layers, using No. 0 chromic catgut for the peritoneum, No. 000 chromic catgut for the subcutaneous tissue, No. 1 chromic catgut for the fascia and black silk for the skin. The patient left the table in good condition. Postoperatively she was given 1500 cc of 5 per cent glucose in normal saline solution, 11 mg of morphine as needed to relieve pain and 1 cc of ergotrate every 4 hours intramuscularly until she was able to retain tablets by mouth.

The following morning she appeared in good condition and was assisted out of bed, walked a few steps and sat in a chair for 10 minutes. This process was repeated each morning and afternoon, the ambulatory periods becoming longer as her strength returned. The temperature for the first 3 days did not go above 100°F, and from then on it remained normal. She was instructed to be active while in bed and had only slight abdominal distress for the first 3 days. The sutures were removed on the 8th day. The wound was clean and firm, and as the patient's general condition was good she was able to get in and out of bed with slight assistance and had no difficulty in walking. Her appetite was good, and she was allowed to go home.

A postnatal checkup 8 weeks later revealed no evidence of prolapse. The abdominal incision was firm, and there were no abnormalities.

CASE 4 H. B. (43642), a 56-year-old man, was admitted on May 31, 1942, with two large, painful inguinal hernias and a history of asthma and chronic bronchitis. He experienced respiratory distress if kept in a recumbent position for any length of time because he could not clear the mucus that accumulated in the bronchial tree.

On June 1, under nitrous oxide, oxygen and ether, a bilateral repair was done. After dissection of the hernial sac and return of its contents into the abdominal cavity, the sac was ligated at its base by interrupted sutures. A portion of the conjoint tendon, fascia and muscle of the internal oblique was attached to the inguinal ligament by interrupted silk sutures and by a strip of fascia taken from the external oblique, whose medial attachment to the symphysis was not disturbed. It was impossible to secure fascia-to-fascia approximation without placing sutures under tension, so that, in the upper third of the repair the muscle of the internal oblique was attached to the inguinal ligament. The defect in the external oblique was repaired by silk, the subcutaneous tissue was approximated by No. 000 chromic catgut, and black silk was used for the skin.

The patient was out of bed the following morning, walked about the room and spent considerable time in a chair. He required 1 cc. of 1:2000 Prostigmin on the 2nd and 3rd days for relief of abdominal distention. His chronic cough was only partially controlled by codeine. He was unusually active during the 11 postoperative days spent in the hospital.

His physician reported that there was no evidence of recurrence when he was last seen 1 year after the operation.

CASE 5 C. C. (46361), a 71-year-old, well developed but poorly nourished woman, was admitted on July 13, 1943, with a history of vaginal prolapse of 4 years' duration causing increasing discomfort and disability. She consulted her physician, who advised surgery.

The general physical examination was essentially negative, and the findings were consistent with the patient's age. There was complete prolapse of the uterus without ulceration of vaginal mucous membrane or cervix.

On July 15, under nitrous oxide, oxygen and ether, vaginal hysterectomy was done, following the technic of Adams.¹⁵

The 2nd day after the operation she was helped out of bed and walked a few steps. She was up each morning and afternoon for 10 minutes. By the 7th day she was walking with slight assistance and remained in a chair for an hour at a time, although she complained of occasional discomfort in the perineum. There was a rather profuse vaginal discharge, which cleared up slowly, and she chose to remain in the hospital until it was practically gone. She was discharged on August 7.

Her physician reported that her condition has remained excellent, with no evidence of prolapse.

SUMMARY

The dangers of prolonged postoperative bed rest, particularly in the obese and aged, are becoming more generally recognized, and there appears to be a favorable clinical response to early rising.

On the basis of a review of published cases and personal experiences, it seems safe to allow patients out of bed within twenty-four hours after operation in the majority of cases.

MEDICAL PROGRESS

THE PRESENT STATUS OF ANTIMALARIAL DRUGS

L EVERARD NAPIER, C I E, F R C P *

BOSTON

IN RECENT years much has been learned concerning the use of antimalarial drugs. The significant changes that have occurred will be discussed in the following paragraphs.

ATABRINE

Pre-Pearl Harbor Status

At the beginning of 1942, there were a large group of clinicians who had had ten years' practical experience with atabrine (quinacrine, *USP* mepacrin *BP*). Many of these were enthusiastic about the drug, not only because it provided an alternative drug for the treatment of malaria, but because they believed that it had definite advantages over quinine in the therapy, and certainly in the so-called "suppression," of malaria. If these clinicians hesitated to advocate its adoption in complete supersession of quinine, it was because quinine had a brilliant record of three hundred years' service in the treatment of malaria, because the advantages of atabrine over quinine were quantitative rather than qualitative and because it was thought possible, even if not probable, that chemists would soon synthesize some drug that would surpass atabrine in its antimalarial action. There was another reason, a political and economic one: atabrine was for many years manufactured only in Germany, whereas in several malarious countries—for example, India—quinine and the other cinchona alkaloids were already local products, and in others cinchona cultivation was recognized as possible and was being planned. Other physicians, although admitting the efficacy of atabrine, did not share the enthusiasm of their colleagues and did not believe that its introduction constituted a real advance. Still others actively opposed its use and appeared to take a delight in reporting untoward incidents that occasionally occurred during a course of atabrine therapy, often without distinguishing between its by-effects and the complications of the attack of malaria. Among this last group were the diehards who had an almost religious regard for quinine and considered it sacrilege to question its supremacy. These persons—unwittingly, of course—did a great disservice to progress, since much time had to be wasted in overcoming the strong opposition to the wider adoption of this drug, which they had aroused, among both the medical profession and the laity, by ill-advised public pronouncements.

Early Dosage Regimes

The dosage adopted in the initial clinical trials with naturally acquired malaria was necessarily arbitrary (Peter,¹ Napier and Das Gupta,² Napier, Butcher and Das Gupta³ and Green⁴). The majority of the patients in these and the later trials during the early years were Asiatics of small stature, and most of them were partially immune, so that, although the standard dosage adopted as a result of wider clinical experience was slightly larger than that used in the initial trials, it was of the order of a minimal dosage. This dosage was 0.1 gm. thrice daily for five days, occasionally extended to seven days, for therapy, and 0.2 gm. twice weekly for suppression.

Despite the satisfactory results of this therapeutic regime, it was noted that the action of atabrine on the parasitemia and fever was slightly less rapid than that of quinine, and for this reason quinine was sometimes recommended for the first two days of treatment, followed by the usual course of atabrine—for example, in the British Army routine (see below).

Pharmacologic Investigation

The pharmacologist was hampered in the early days by the inadequacy of the methods of determining atabrine in the urine, blood and tissues, he did show, however, that it appeared in the urine within a few minutes, whether the drug was given by mouth or intramuscularly, that traces could be detected there for some time, and that it accumulated in the tissues, but he did not provide any data to encourage the physician to modify his empirically adopted dosage routine.

When in 1942 Japan took Java, whence had hitherto come ten elevenths of the world's supply of quinine, the spotlight of medical research was naturally focused on atabrine, the only known synthetic substitute for quinine. After a little valuable time had been lost, on both sides of the Atlantic, by the not unnatural official hesitancy, in view of the doubts expressed by others, to accept atabrine at the value placed on it by the enthusiasts, the plans for its large-scale production were put into operation. At the same time intensive work on the pharmacology of atabrine was undertaken and important results were obtained at an early date. In a world now extremely plasma-level conscious

*Visiting lecturer, Department of Comparative Pathology and Tropical Medicine, Harvard Medical School and Harvard School of Public Health.

†These workers gave 0.6 to 1.2 gm. in four days.

as a result of several years' experience with the sulfonamide drugs, it is not surprising that one of the earliest investigations was aimed at measuring the plasma level achieved by different dosage regimes and the minimum plasma level that is necessary to control the malarial attack. This work was aided by the fact that the methods of accurately estimating atabrine in the body fluids and tissues were much facilitated by the comparatively recently introduced photoelectric and other fluorimeters.

These studies, including that of Shannon et al.,⁵ led to some important observations, which can be summarized as follows:

The chemotherapeutic activity of atabrine is a simple function of the plasma concentration.

A large percentage — of the order of 90 — of the atabrine taken by mouth or given intramuscularly is fixed in the tissues, and about 3 per cent is excreted in the urine and 6 per cent in the feces in the first twenty-four hours. After administration is discontinued, the rate of excretion falls off rapidly, but traces are found in the urine for many weeks.

On the ordinary daily dosage of the earlier therapeutic regimes, the maximum plasma level is not attained for several days, but once a balance between the intake on the one hand and the rate of excretion and degradation on the other has been achieved, a fairly uniform level in the plasma may be expected. In a large group of persons taking atabrine daily, the mean plasma level is proportionate to the daily dose, but among subjects on the same dose the levels vary considerably, between extremes this variation may be fourfold — for example, from 30 to 120 gammas per liter after 0.3 gm. atabrine daily. In persons taking a regular daily dose, the general rule is that 40 per cent of the final level is reached at the end of the first day and 40 per cent of the deficit is made up each day subsequently, so that 90 per cent of the peak level is attained by the end of the fourth day. If, however, the dosage on the first day is doubled, this plasma level is attained at the end of the second day, and if it is trebled, this near peak is attained on the first day, and the peak level (for that particular dosage) can be maintained subsequently by the ordinary daily dosage. Conversely, when the drug is discontinued, the falling off in plasma level is at the rate of about 20 per cent daily for several days, but traces of atabrine are still present even after eight weeks.

In the suppressive regime of 0.4 gm. weekly, it has been found that the peak level of between 8 and 15 gammas is obtained about the end of the fourth or fifth week, however the dosage is divided, but that by increasing this to 0.6 gm., given in six doses, a level of the order of 15 to 30 gammas, with a mean above 20, is reached within the same period.

The behavior of atabrine is thus in sharp contrast to that of quinine (see below), which appears very early in the blood in relatively much higher concentrations, reaches its peak concentration in about four hours, and falls far below the therapeutic level by the end of twenty-four hours.

The plasma concentration of atabrine necessary to effect a clinical cure in malaria varies both with the host and with the strain of parasite, but it is generally concluded that a minimum level of 30 gammas is required. For suppression, a breakthrough* does not usually occur when the plasma level is above 12 gammas.

Clinical Experience

Field experience with totally nonimmune members of the British, Australian and American fighting forces, who were on the average considerably heavier and better nourished than the often partially immune Asiatics who had formed the bulk of the clinical material on which the earlier dosage regimes had been calculated, soon showed that these dosage regimes were inadequate from the point of view of both treatment and suppression. It also confirmed the opinion held by many of the earlier workers that the importance of the by-effects of atabrine therapy should not be overemphasized, and indicated that these by-effects are less likely to occur in better nourished persons, that some of them can be obviated by such simple measures as taking sodium bicarbonate or glucose at the same time, that most of them — for example, the gastrointestinal disturbances and the mild psychoses that sometimes follow the early doses — frequently do not occur later during the course when some tolerance for the drug has been established (Green⁶) and that they are therefore not an indication for discontinuing the drug altogether, nor even, except in rare cases, for modifying the dosage.

Dosage Revision

The advisability of increasing the dosage of atabrine thus became obvious, and the data that had meanwhile been accumulated made it possible to introduce a rational regime in place of the earlier empirical one. The most important modification that the pharmacologic investigations had indicated was the principle of "loading" the dosage during the early hours of treatment. This applies whether the drug is given by mouth or parenterally. The dosage recommended by the United States Army exemplified this principle. It prescribed the giving of 0.2 gm. of atabrine immediately and every six hours night and day during the first twenty-four hours, a total of 1.0 gm., and reverting to the three-times-daily dose of 0.1 gm. for another six days, that is, 2.8 gm. in all.

*A term indicating the development of clinical malaria during an established suppressive course.

For parenteral medication it is better to use the intramuscular route, since it has no disadvantages as compared with the intravenous one and is probably safer, by the latter route extremely slow administration is essential. In cases in which parenteral therapy is indicated, — for example, in the unconscious patient, — two injections of 0.2 gm. of atabrine in 5 cc. of distilled water are given into the buttocks, one on each side. Administration by the oral routine should be begun as early as possible, but, if for any reason this is delayed beyond six to eight hours, another intramuscular injection should be given and repeated every eight hours until oral therapy can be instituted. To ensure the necessary "loading," the oral dosage prescribed must be such that the total atabrine given in the first twenty-four hours amounts to 1.0 gm., and the usual 0.1 gm., thrice daily, is continued. (For smaller and less well nourished persons some modification of the dosage is necessary, but the loading principle should still be followed.)

This atabrine course does not by any means preclude relapses in natural infections of any of the three commonly encountered malarial species, but it is more effective in this capacity than is quinine or the other cinchona alkaloids, and it results in a longer initial period of freedom from relapses and wider spacing of subsequent relapses in benign tertian malaria, this is to some extent due to the slow rate of excretion of atabrine and its presence in the blood in appreciable quantities for several weeks. In malignant tertian malaria a second course of atabrine after an interval of ten days often results in a radical cure of this infection.

For suppressive therapy a daily dose of 0.1 gm. is given if this regime can be started not less than two weeks before the subject enters a malarious area, but if an earlier entry is likely, the loading principle should be achieved either by doubling the daily dose for the first week and continuing on the usual daily dose of 0.1 gm. or by giving a single loading dose of 0.6 gm. before commencing the ordinary regime (Medical Research Council recommendation).

So-Called "Practical Prophylaxis" in Malignant Tertian Malaria

There is no drug that acts as a true prophylactic in malaria and destroys or prevents the further development of the sporozoites injected by the mosquito. The failure of quinine to do this has been recognized for many years, and it has been repeatedly shown that nonimmune persons subjected to *Plasmodium vivax* infection during a suppressive course of atabrine, although they remain free from clinical symptoms while on the suppressive treatment, invariably come down with a clinical attack of malaria between the second and fourth weeks after they discontinue the suppressive regime. It has,

however, been shown that practical prophylaxis, at least against the South Pacific strains of *P. falciparum*, can be achieved, — that is to say, by giving 0.1 gm. of atabrine daily for two weeks before and twenty-three days after subjection to a heavy infection by this parasite, the subject is protected from any clinical manifestation of malaria, — and that after the drug is discontinued this freedom from clinical malaria lasts indefinitely unless the subject is reinfected. That this is only practical prophylaxis and not true prophylaxis entailing destruction of sporozoites is shown by the fact that early development of the schizogony cycle does actually take place, — as proved by blood-inoculation experiments, — but it does not reach the clinical threshold.

To summarize, it has been shown that in the administration of atabrine for both the suppression and the cure of malaria, by the adoption of more rational regimes, indicated by recent investigations, most of the disadvantages hitherto associated with its use can be overcome, and that in both capacities, and unquestionably in the former, it is the drug of choice. Given in suppressive doses it is apparently a practical prophylactic in *P. falciparum* infections of the South Pacific.

PLASMOCHIN

Plasmochin (pamaquine, *USP* pamaquin, *BP*) was introduced by Schulemann, Roehl and their co-workers (Roehl¹⁷) at Leverkusen in 1924 as a synthetic substitute for quinine, after preliminary screening experiments with *P. relictum* infections in canaries. It did not live up to the early claims made for it by its introducers, but it did find a place in the therapeutics of malaria. It was soon shown that by itself it was not a practical drug for use in the treatment of the malarial attack. It stopped the schizogony cycle and cured the clinical attack in both benign tertian and quartan malaria, but only when given in large and toxic doses, and even in these doses it did not affect the clinical attack or the schizogony cycle in malignant tertian malaria. On the credit side, however, it was found to destroy, or at least sterilize, the circulating gametocytes, particularly in malignant tertian infection, in small and perfectly safe doses — 0.01 gm. twice daily for three days. Although gametocyte destruction is not a measure that in any way aids the patient, it is in certain circumstances an important precaution as a prophylactic measure for the general population in a malarious country, and in this capacity plasmochin occupies a unique position, even today, because neither atabrine nor quinine achieves this. Further, it was found that although little was gained by adding plasmochin to quinine so far as the current attack of malaria was concerned, it was of value in reducing the number

of relapses in benign tertian malaria,* but here again only when given in doses that were toxic to the majority of the subjects, and so toxic to a few that the treatment had to be abandoned.

When atabrine was introduced, the assumption that this drug could be used instead of quinine in the quinine-plasmochin antirelapse regime was somewhat too readily assumed. It was believed that the toxicity of each drug was enhanced by its association with the other, so that the dosage of plasmochin was whittled down and it was given separately instead of coincidentally with atabrine. Claims for the relapse-preventing properties of the plasmochin-atabrine combination† were not of the same order as those made for large doses of plasmochin and quinine, but undoubtedly some of the aura that had been generated by the latter gathered around the former combination, and an exaggerated idea of the value of the addition of plasmochin to the course of atabrine was widely diffused through the medical literature. This impression was fostered by the adoption at the outset of the present war of the so-called "2525"‡ regime by the Royal Army Medical Corps and the similar quinine-atabrine-plasmochin regime of the United States Army Medical Corps, so that it came as somewhat of a surprise to many when the Army treatment regimes were revised and plasmochin was dropped altogether. This gave plasmochin a bad name that it had certainly not earned, and led to such statements by the ill-informed as "Plasmochin has proved a failure" and "Plasmochin has not lived up to its reputation." The fact was that the Army authorities realized that there were few circumstances in which there was much to be gained by destroying the gametocytes whose destruction could in any case be achieved by a smaller dosage of plasmochin, that the antirelapse properties of this small dosage were

at the best extremely slight in benign tertian and were nonexistent in malignant tertian infections and that it was not worth prolonging the treatment regime and risking toxic symptoms in the few persons who had an idiosyncrasy, for such questionable advantages. Plasmochin is still, however, the only drug that clears the blood of malignant tertian gametocytes¶ and in combination with other drugs prevents relapses in benign tertian malaria, or at least cuts them down to an extremely low percentage. One ought perhaps to return to the surer ground of the plasmochin-quinine combination and test the effect of a safe plasmochin dosage, that is, 0.01 gm thrice daily, given coincidentally with quinine, over a longer period, say ten to fourteen days.

But this is not all. James and his co-workers¹⁴ showed that by giving large doses of plasmochin (0.08 gm daily for three days and 0.06 gm for five, a total of 0.54 gm) before and immediately after infection with benign tertian sporozoites, practical prophylaxis could be achieved, although they failed to produce this effect consistently with smaller, even though still toxic, doses, namely, 0.06 gm daily for seven days. In the cases in which prophylaxis failed, the subjects had their first clinical attacks nine months after infection.

There is thus reason to believe that, although the practical use of plasmochin is limited by its high toxicity, it is in several ways a unique drug, in that it affects certain stages of both benign and malignant tertian parasites that are unaffected by the other antimalarial drugs now in use. It is hoped that, with plasmochin as an example, it will in time become possible to synthesize a quinolin derivative with the same therapeutic potentialities as plasmochin but without its limiting toxicity.

QUININE AND OTHER CINCHONA ALKALOIDS

Whereas the cinchona alkaloids have been in use for over three hundred years, the alkaloid quinine has occupied its special privileged position for less than a hundred years. The scientific basis for the choice of this alkaloid was probably sound, but the circumstances that placed it in such a position of dominance were unfortunate, for they led directly or indirectly to the development of a monopoly that had repercussions that have in turn proved disastrous to the outside world and to the monopolists themselves.

The climate in Java was such that it was possible to grow a particular variety of cinchona, *Cinchona ledgeriana*, which gave the richest yield of quinine, so much more easily than elsewhere that the large cinchona plantations in Ceylon, India, South America and elsewhere were eventually driven out.

¶The closely allied Cilonal, which has never been issued for general use, also achieves this but otherwise has no advantage over plasmochin and so possibly do some of the other recently discovered drugs.

*Sinton and Bird⁸ showed that when a course consisting of 0.10 gm. of plasmochin and 1.25 gm. of quinine daily for twenty-eight days was given to 20 soldiers with benign tertian malaria no relapses occurred, and that when the dosage of plasmochin was reduced to 0.06 gm daily in smaller subjects and the drugs were given for a total of seventeen days (with various intervals) to 15 soldiers only three relapses occurred. That is, in 35 cases there were three relapses, a rate of 9 per cent, compared with a rate of 77 per cent in a series of 111 cases in which quinine was given in the usual doses. Sinton, Smith and Pottinger⁹ also had no relapses in a series of 17 patients given 0.06 gm. plasmochin and 1.31 gm. of quinine for twenty-one days. All the subjects in these experiments and the controls were under military discipline and were kept under clinical and parasitologic observation for a minimum of two months, although this did not preclude the possibility of a late relapse, at least the controls showed a high percentage of relapse within these two months. In India a course of 0.04 gm. of plasmochin and 1.31 gm. of quinine for three weeks was given to all soldiers both British and Indian with a benign tertian infection, with highly satisfactory results in a group of over 3000 cases—so satisfactory in fact that in 1934 the convalescent depot at Kasauli where much important experimental work on antirelapse therapy had been done since 1924 had to be closed on account of the paucity of cases of relapsing benign tertian malaria. Since the fall in incidence preceded the adoption of atabrine, it was attributed by the Army authorities to plasmochin administration (Amy and Boyd¹⁰). Toxic effects were, however, not uncommon (Manifold¹¹).

†In 1933-1934, Bird¹² in a series of trials in India showed that by giving 0.01 gm. thrice daily for five days after the course of atabrine, the relapse rate in benign tertian infection was reduced to 50 per cent, as against 45 per cent for quinine with the same plasmochin dosage; the groups comprised 150 and 200 cases respectively. Gentzkow and Callender¹³ also effected a distinct although not spectacular reduction in the recurrence rate among military personnel in Panama by adding 0.01 to 0.02 gm of plasmochin to the atabrine course thrice daily for three to five days.

‡Two days of quinine five days of atabrine two days of rest and five days of plasmochin.

of business. The price of quinine was then raised to a level that made it difficult for the malaria sufferers in poor countries to afford the amounts of this drug that they needed.

It has long been appreciated that the other crystalline alkaloids of cinchona bark also have high anti-malarial properties, and an attempt has been made in several countries to introduce a mixture of cinchona alkaloids—for example, the total crystalline alkaloids of the bark of certain hardier cinchona trees, *C. robusta* and *C. officinalis*—for general use against malaria. This scheme was fostered by the Health Organization of the League of Nations. The main obstacles to the more general adoption of the mixed alkaloids were the conservatism of the medical profession and the vested interests of the cinchona planters. The result was that when the Java plantations were taken by the Japanese early in 1942, little progress had been made in the scheme for extending the cinchona plantations in any of these countries. Nevertheless, it was believed that the possibilities should be further explored, and as a part of the research program further studies in the pharmacologic and therapeutic properties of the cinchona alkaloids were undertaken.

Pharmacology

As noted above, the peak plasma concentration of quinine is reached within four hours of the oral administration of this alkaloid, but the concentration falls rapidly. This means that it is a useful drug for its quick action but that continuous administration is essential for the action to be maintained. After the routine administration of quinine—1.3 to 2.0 gm. daily in two or three doses—the plasma concentration reaches 3 to 10 mg. per liter and remains there.

The efficient therapeutic level varies for different hosts and for different species and strains of parasite, it is of the order of 3 to 5 mg. per liter but rises to 10 mg. for quinine-resistant strains, especially those of *P. falciparum*. It is, however, essential that this level be maintained for several days.

The rate of absorption and the levels of plasma concentration of quinidine and cinchonidine were found to be similar to those of quinine, but the rate of absorption of cinchonine appeared to be much slower and less complete. It was shown, however, that the absorption of cinchonine was actually as complete as that of quinine, but that its rate of degradation was much higher. As a result, the plasma level was only a fraction of that of quinine after the same oral or parenteral dose. On the other hand, the therapeutic activity of cinchonine was much greater than that of quinine, a plasma concentration of 0.3 mg. per liter maintained for four days being curative in benign tertian infections. The higher therapeutic activity of cinchonine thus fully compensates for the low plasma level, and the final result of the oral or parenteral administration

of equal doses of the two drugs is the same, with perhaps a slight clinical advantage for cinchonine on account of its lower toxicity.

Clinical Experience

The Madras (India) Cinchona Commission in 1867–1868 first reported that the actions of the four principal cinchona alkaloids, quinine, quinidine, cinchonidine and cinchonine, on “malarial fever” were equal. This observation was confirmed later by several observers, including Sinton and Bird.¹⁴ As a result of the renewed interest in this subject, further investigations were undertaken in the United States and Great Britain. All these confirmed the previous opinion that each of the other three crystalline alkaloids has approximately the same anti-malarial action as has quinine. Field experiments also showed that a totaquine* mixture consisting of about 70 per cent total crystalline alkaloids was as effective as quinine alone in approximately the same dosage. It was, however, noted that the disagreeable by-effects were more frequent with totaquine, and it was once again concluded that these were mainly caused by the amorphous alkaloids in the mixture. On the other hand, there was no evidence that any one of the crystalline alkaloids or any combination of them was more effective than quinine in preventing relapses, or that any of them would act as a true causal prophylactic.

Since the peak plasma level is reached so soon, an initial loading of the dosage is unnecessary, and probably inadvisable, in the treatment of Asiatics of small stature with quinine or the other cinchona alkaloids, but for nonimmune white troops the Army practice is to give 1 gm. thrice daily for two days and 0.67 gm. thrice daily for the next five days. I believe that this is only to be recommended in malignant tertian infections.

As a suppressive drug, quinine was used extensively in World War I by the British and French in Macedonia. Its practical failure in this role was attributed to the failure to see that the troops took the drug properly, since for many years before and after 1918 it had been used extensively in civil life in the tropics, in some cases with a considerable degree of success. Since Pearl Harbor, not much quinine has been available for use as a suppressive, but on the few occasions on which it was used it was not a conspicuous success. Its pharmacology makes this understandable, and since there is no reason to believe that any of the other alkaloids would be more active, it seems probable that in this capacity the cinchona alkaloids will have to give way to one of the synthetic drugs, atabrine or its successor.

To summarize, recent experience in the laboratory and field has made no material difference in opinions concerning the value of quinine and the other cin-

Totaquine is the name suggested by the Health Organization of the League of Nations for a standardized mixture of the alkaloids of cinchona. This is the official B.P. designation, the U.S.P. one being, totaquine.

chona crystalline alkaloids, although further scientific evidence has been provided to show that all the crystalline alkaloids of cinchona are equal in their antimalarial activity, and that a mixture of these alkaloids can be used as a completely efficient substitute for the single alkaloid quinine

OTHER SYNTHETIC ANTIMALARIAL DRUGS

Another line of investigation has been the search for new synthetic antimalarial drugs. Many such drugs have been synthesized, and some have been shown to possess antimalarial properties equal to and even greater than that of atabrine, but their superiority has been quantitative rather than qualitative, and up to the present no one has been found that does what atabrine does not do, namely, destroy the sporozoites or prevent relapses in benign tertian malaria

It is probable that if no better drug is found some of these will be manufactured and marketed after the war, but the authorities in the Allied countries have wisely decided that, in view of atabrine's background of fifteen years of laboratory and clinical trial, it would be foolish to change over to some other drug for the sake of apparent minor advantages, without the knowledge of its limitations that only long experience can provide

CONCLUSIONS

Prior to 1942, atabrine was looked on as a valuable addition to the armamentarium of the physician for the cure and suppression of malaria, but its place was certainly second to that of quinine. Recent work has shown that it is probably the most valuable drug in the fight against malaria

Despite the fact that quinine and the other cinchona alkaloids have had to take a place below atabrine on the antimalarial priority list, recent work has in no way questioned their efficacy. On the contrary, it has confirmed previous work regarding the antimalarial activity of all the crystalline alkaloids, and more especially that of a mixed alkaloidal preparation, which in some of the poorer malarious countries may, on economic grounds, still prove to be the drug of choice for the mass of the population

The strict limitations of plasmochin in the treatment of malaria have long been recognized, and recent experience has merely served as a reminder of these limitations. It is, however, the only drug that acts as a true causal prophylactic or actually prevents relapses in benign tertian malaria, albeit

in large and dangerous doses. These unique properties should be recognized and, in special circumstances, full advantage taken of them. Furthermore, it seems possible that by a modification of the formula of plasmochin a less toxic but equally efficacious drug may be synthesized. The discovery of such a drug will give man a weapon with which he will be able to control malaria not only in the individual but in the community. Although it is improbable that malaria will ever be banished by the use of drugs alone, with a drug possessing these properties it may be possible to control it in some communities where this was hitherto impossible, and in others to do so more effectively and at lower cost than would be possible by any other means. Until, however, such a drug is discovered no claim for man's mastery over malaria can be made

It will be surprising if the intensive chemical and medical research that is now being carried on in several countries does not lead to the discovery of a synthetic drug in which all the qualities of the known antimalarial drugs are combined with some unique ones of its own. Meanwhile, there are three valuable antimalarial drugs: atabrine, the cinchona alkaloids, including quinine, and plasmochin. Each has its own place in the treatment of malaria

CASE 31281

PRESENTATION OF CASE

A forty-five-year-old hospital attendant was admitted because of an increasingly productive cough.

About one and a half years before admission the patient began to notice painless swelling of the finger tips and stiffness in the knees. The limitation of motion slowly progressed to involve the ankles, wrists, elbows and interphalangeal joints of the hands and feet. These joints were never red or hot. The stiffness was accompanied by dull constant pain, which diminished somewhat with use. Gradually the involvement of the upper extremities subsided, but the knees and ankles became very swollen and exquisitely painful and the limitation of motion progressed. There was still no redness or heat. Two months before admission he was advised to have his remaining teeth extracted. This he had done. About a month before entry, without chills, fever or chest pain, he developed a productive cough, which soon daily yielded 200 to 400 cc of whitish, non-blood-streaked phlegm. He also began to have night sweats two or three times a week. During the nine months before admission he had complained of dyspnea on exertion, which did not progress. His appetite had remained good, but during the previous one and a half years he had lost 15 pounds.

There was no history of gonorrhea or exposure to tuberculosis. For many years the patient had imbibed freely of rum.

Physical examination revealed an emaciated, moderately dyspneic, edentulous man in considerable discomfort because of painful legs. He showed definite gynecomastia. Expansion of the chest was symmetrical, and the chest appeared to be fairly emphysematous. Rhonchi and wheezes were heard over the entire chest posteriorly but were most pronounced at the bases. Tactile and vocal fremitus and resonance were normal. The abdominal wall showed considerably dilated veins. The liver and spleen were not enlarged. The knees, ankles, feet and all toes showed marked swelling, tenderness and pain on motion. The skin over these areas was tense, glossy and light pink. There was no redness or heat but marked hyperhidrosis. The patellas were definitely elevated and ballotable, and a fluid

wave could be obtained over the knee joints. The swelling over the legs, ankles and dorsums of the feet was firm and did not pit. The fingers and toes showed clubbing of an advanced degree.

The temperature was 99.5°F, the pulse 90, and the respirations 20. The blood pressure was 112 systolic, 80 diastolic.

Examination of the blood showed a red-cell count of 4,700,000, with 11 gm of hemoglobin, and a white-cell count of 10,500, with 77 per cent neutrophils. The urine was normal. The serum chloride was 95 milliequiv per liter, the prothrombin time 22 seconds (normal, 18 to 20 seconds), the protein 4.8 gm per 100 cc, the calcium 6.6 to 8.3 mg per 100 cc, the phosphorus 3.1 mg, the cephalin flocculation test + in forty-eight hours, the alkaline phosphatase 4.1 units per 100 cc, and the corrected sedimentation rate 17 mm per minute. The stool was normal. Synovial fluid drawn from the left knee was slightly cloudy and pale yellow, and most of it promptly clotted. It contained 100 white cells and 700 red cells per cubic millimeter (of the former, 20 per cent were polymorphonuclear cells and 80 per cent were monocytes) and 106 mg of sugar (serum sugar 136 mg) and 2.2 gm of protein per 100 cc. Repeated sputum cultures showed few beta-hemolytic streptococci, a few staphylococci and no pneumococci, spirochetes or other pathogens of significance. The Hinton test was negative. A 1:10,000 tuberculin test showed a 1.0-cm area of redness with a 0.5-cm central zone of induration. A bronchoscopic examination was negative, except for the presence of an increased amount of thin white secretion.

X-ray studies showed slight decalcification of the bones of the hands, arms, knees and feet. There was an extensive feathery periosteal proliferation involving the majority of the bones. This had the characteristic appearance of pulmonary osteoarthropathy. The chest films showed a homogeneous shadow of increased density with somewhat ill-defined margins in the axillary portion of the left upper lobe. No definite fluid level was seen. The diaphragm, heart and aorta appeared normal.

Throughout the patient's course in the hospital the temperature was normal except for an occasional low-grade fever, which rarely reached 101°F. The pulse was somewhat elevated, usually between 90 and 110, and the respirations were normal. He produced from 60 to 400 cc of white nonpurulent sputum daily. His appetite remained fair, and he lost no further weight.

After the second week he was given approximately 100,000 units of penicillin per day. Aspirin fairly well controlled his joint discomfort. A cephalin flocculation test repeated during the third week was +++ in forty-eight hours. The prothrombin time was 31 seconds (normal, 18 to 20 seconds). During the fifth week the calcium was 8.3 mg per 100 cc and the protein 6.0 gm per 100 cc. X-ray films of the chest repeated four and six weeks after ad-

*On leave of absence.

mission showed a rather marked increase in the size of the lesion in the left upper lobe on each occasion (Fig 1) The patient insisted that his joints were less painful and that he felt generally better The urine remained normal, except for a ++ test for urinary calcium (Sulkowitch test) The white-cell count rose briefly to 23,800, with 83 per cent neutrophils

He was given several whole-blood transfusions and was maintained on daily penicillin, Synkovite

The symptoms and signs in this case center around three systems — the lungs, the liver and the joints It would be nice if we could find a diagnosis to cover all three systems The chances are that we shall not be able to We might rule out some diagnoses right away and include others I think one can rule out pulmonary tuberculosis simply because the x-ray appearance is not characteristic and because the negative sputum and the past history are against it The patient undoubtedly had pulmonary

FIGURE 1 *Roentgenogram of Chest*

and Hykinone for two weeks On the thirty-first hospital day an operation was performed

DIFFERENTIAL DIAGNOSIS

DR JACOB LERMAN One point in the history worth commenting on is that the patient noticed painless swelling of the finger tips one and a half years before entry If that is an accurate observation, then we can date the beginning of clubbed fingers It is not infrequent, however, for a patient to mistake the terminal joint for the tip of the finger, so that the patient's statement, unless he was sure of it, may be a source of error I shall assume, however, that he had clubbed fingers beginning one and a half years ago

osteoarthropathy That diagnosis is given to us It was an extensive type of pulmonary osteoarthropathy He certainly had some form of liver disease He had a high alcoholic intake, dilated abdominal veins and gynecomastia, which are important in the diagnosis of liver disease The blood chemistry is also consistent with liver disease The prothrombin time was elevated, the serum protein was low, and the cephalin flocculation test was positive We presume that they looked carefully for varices of the esophagus, which were not found, unless they were so sure of the diagnosis that they deemed it unnecessary to look We may conclude that he had characteristic portal cirrhosis

As so often happens in these cases with longstanding pulmonary disease associated with liver

disease one has to include amyloid disease in the differential diagnosis. There is, however, a good deal of evidence against amyloid disease. In the first place, the liver and spleen were not enlarged. Enlargement of these organs is a common finding in amyloid disease. Furthermore, there is no mention of the Congo red test. If it had been done I assume that it was negative. If it had not been done then certainly they did not think much of this diagnosis. My first impression in reading the story was that this patient did not have amyloid disease.

Could he have had rheumatoid arthritis? The history is consistent with this diagnosis except for the onset of clubbed fingers one and a half years previously. I am inclined to believe that the joint symptoms were part of the picture of chronic pulmonary osteoarthropathy rather than ordinary rheumatoid arthritis. As to the nature of the lung condition itself, before we go farther, I should like to see the x-ray films, particularly those of the lungs.

DR GEORGE W. HOLMES: The changes in the periosteum are well marked and extensive. It is a characteristic picture. I believe that one can say, so far as one can see on the x-ray films alone, that the whole picture in the joints was due to pulmonary osteoarthropathy. There is no evidence of rheumatoid arthritis. The joint spaces are not narrowed. If he had had rheumatoid arthritis for one and a half years there should be more evidence in these films.

In the chest there is a lesion that apparently lies outside the bronchus. It does not seem to interfere with the passage of air through the bronchus because the lungs and diaphragm move normally. There is no mediastinal shift. Furthermore, so far as I can make out, there are no metastatic masses or enlarged hilar lymph nodes. The lesion is definitely lobulated and the margins are not distinctly seen, but there is no cavity. It is possible, even with a homogeneous picture like this, that the cavity is completely filled with fluid. I presume that every effort was made to demonstrate a cavity because of the history of having had his teeth extracted.

We have no evidence that the bronchus is obstructed. The location of the tumor is of some interest. Apparently it is in the midportion of the chest, within the lung. It does not seem to reach the pleura, except at this point. Of course it would be helpful if I could tell you whether it is benign or malignant, and if the latter, whether it is primary or metastatic, but I cannot.

DR LERMAN: Dr. Holmes has been of help in one respect. He agrees that there is no rheumatoid arthritis and that this part of the picture is part of the syndrome of pulmonary osteoarthropathy.

What is the possibility of pulmonary suppuration? The patient had symptoms following the extraction of teeth but did not have chills or fever, and the chest films did not reveal an abscess cavity. Consequently we do not have sufficient evidence to make a diagnosis of lung abscess. Moreover, the pul-

monary osteoarthropathy in all probability antedated the development of the pulmonary symptoms. I think one may say that pulmonary abscess does not play an important role here unless there was an abscess caused by the breakdown of a tumor. Similarly we can discard an encapsulated empyema. There is no previous history of pulmonary infection, nor did this process displace the mediastinal contents as it progressed. Certainly the patient did not have the characteristic chills and fever and was not so sick as one would expect him to be with an encapsulated empyema.

The major problem is to decide whether this was a benign or malignant tumor. The presence of chronic pulmonary osteoarthropathy of an extensive sort favors a malignant tumor of the lung rather than a benign one, although I have seen one patient with an adenoma of the bronchus who had an extensive pulmonary osteoarthropathy. The rapid spread during the course of observation favors the diagnosis of malignant tumor. The long duration of pulmonary osteoarthropathy does not rule out malignancy but merely means that the tumor was of a slowly growing type. It is somewhat unusual for a malignant tumor not to show by x-ray some evidence of its character. I should say that, by and large, bronchoscopy should have revealed something of the nature and origin of this tumor if it were malignant unless it was in such an awkward position that the bronchoscopist could not see it.

I should like to digress a moment to discuss the relation between malignant tumor of the lung, gynecomastia and osteoarthropathy. There are descriptions in the literature of malignant tumor of the lung, chronic pulmonary osteoarthropathy of a severe nature and gynecomastia. This happens to be a case in point. It would be nice to put them all together. We have assumed that gynecomastia in cases of cirrhosis of the liver is due to failure of the liver to conjugate the steroid hormones, particularly estrin. This results in excessive amounts of estrin in the blood. One may theorize further that excess estrin, or some other steroid, may reach the terminal portions of the bones and produce changes in the periosteum characteristic of pulmonary osteoarthropathy. We know that these steroids have definite actions on the calcium metabolism and on the deposition of matrix in the bone. Failure to neutralize the steroid hormones might explain clubbing in cases in which some form of liver disease is present, but what about those that do not have obvious liver disease? One possible assumption in these cases is that malignant tumors of the lung frequently develop necrosis and suppuration, which may produce amyloid changes in the liver and simulate the functional disturbance present in cirrhosis. I merely interject this as a possible explanation. At grand rounds this morning a patient of Dr. Chester M. Jones was presented who had pulmonary osteoarthropathy and diarrhea, the latter probably

associated with a deficiency state. Here again is an ideal setup for liver disease and the development of pulmonary osteoarthropathy on the basis of the mechanism just proposed. It would be valuable support for this theory if Dr Jones's patient had gynecomastia, but unfortunately he does not.

DR BENJAMIN CASTLEMAN The twenty-four-hour excretion of 17-ketosteroids was 7.6 mg corrected and 8.6 mg uncorrected.

DR LERMAN That is a normal range for a patient who is sick. This test does not tell us about the excretion of other steroids, particularly estrin.

Unfortunately there is no easy test for estrin compounds. It necessitates a good deal of biologic testing and little of it is done. Nor is there an easy test for the progestin compounds, which may be present in male urine.

The second question is whether this was a primary or a metastatic lesion. One might speculate on the possibility of a metastatic lesion from the liver. We know that the patient had cirrhosis, and portal cirrhosis is frequently a precursor of hepatoma. This might, therefore, be a metastatic lesion from the liver. There is, however, no mention in the record of an abnormal mass in the liver. The liver was not palpable. This is against the diagnosis of hepatoma. Moreover, it seems unlikely that a secondary lesion from the liver could have gone on for a year and a half without producing evidence of metastatic lesions elsewhere in the body. It is an unlikely but a plausible way of tying in all three systems.

I believe that this patient had a malignant lesion of the lung, most likely a carcinoma but possibly some form of sarcoma, associated with pulmonary osteoarthropathy of long standing, and an independent portal cirrhosis.

DR RICHARD H. SWEET The findings at operation are often of much less importance than the necessity for making an accurate preoperative diagnosis. This case was presented to me as one of lung abscess. I did not accept that diagnosis, but I should like to point out the importance of making sure.

This man was in such poor condition that I was in no haste to operate. It took a good deal of prodding on the part of the house staff to get me to consent to operate at all. You can readily see that in a patient in such poor condition it is essential to determine the type of procedure beforehand, if it were an abscess one could do nothing but make an incision and drain, whereas if it were carcinoma one would do an open exploration. I throw that in for what it is worth. I came to the conclusion, as Dr Lerman did, that it was carcinoma, and used the extreme degree of pulmonary osteoarthropathy in making the diagnosis. We performed a total pneumonectomy.

CLINICAL DIAGNOSES

Carcinoma of lung
Pulmonary osteoarthropathy

DR LERMAN'S DIAGNOSES

Malignant tumor of lung, probably carcinoma
Pulmonary osteoarthropathy, chronic
Portal cirrhosis

ANATOMICAL DIAGNOSES

Adenocarcinoma of lung
Pulmonary osteoarthropathy, severe

PATHOLOGICAL DISCUSSION

DR CASTLEMAN This was a large granular tumor through which many small bronchi traversed (Fig 2). There was, however, no obstruction to the large

FIGURE 2 Photograph of Cross Section of Resected Left Lung

bronchi, although one of the bronchi in the posterolateral segment of the upper lobe did contain a nodule eroding the mucosa, which suggests a bronchiogenic origin. It is interesting to note that the tumor crossed the septum and extended for a short distance into the apex of the lower lobe. Microscopically the tumor turned out to be a low-grade adenocarcinoma. We have found that adenocarcinoma of the lung rarely occurs at the hilus, as in this case, usually being located more peripherally than are the epidermoid and oat-cell cancers. There was also a small metastasis in the lower lobe.

This man died soon after operation, and at autopsy we found a large metastasis in one of the adrenal glands. The sections of the breast showed a rather extreme degree of gynecomastia. In this

connection Fried* has reported 4 cases of carcinoma of the lung with pulmonary osteoarthropathy and some endocrine disturbance, such as gynecomastia. He also found that in some of these cases the anterior portion of the pituitary gland was increased in size, and in some the eosinophilic cells were increased in number. In this case, however, the pituitary gland was of normal size, and although I did not really count the cells, there did not seem to be an increase in the number of eosinophilic cells.

DR LERMAN: How about the liver?

DR CASTLEMAN: There was no cirrhosis or any evidence of chronic disease. There was some central congestion and necrosis, which was probably terminal.

DR MARIAN W. ROPES: It is surprising how many patients with pulmonary osteoarthropathy come in with a diagnosis of rheumatoid arthritis.

DR CASTLEMAN: We examined some of the bones microscopically and found all stages of periostitis—from the radiating fibrillar strands out from the cambium or inner periosteal layer to osteoid formation and, finally, calcification and fusion with the cortex.

CASE 31282

PRESENTATION OF CASE

A sixty-seven-year-old, invalid woman was admitted to the Emergency Ward at midnight because of hematemesis.

About six years before admission the patient had an episode of severe hematemesis, and about four months before entry she had another. On both occasions she was admitted to a hospital and carefully examined. The source of the hemorrhages could not be discovered. Four hours before admission to this hospital she had vomited a large amount of bright-red blood with clots. She became weak and apprehensive. A physician gave her a "hypodermic." Three hours later she came to the hospital. She had had rheumatoid arthritis for many years, and for the past eighteen years had been completely confined to a chair-and-bed existence. In addition to the above-mentioned hematemesis she had had other episodes of vomiting small amounts of blood. She had had no epigastric distress at any time and had never noted tarry stools. For many years she had taken an occasional aspirin tablet, which caused no gastric discomfort. There had been no awareness of fever. During the previous six months she had become somewhat anorexic. She had lost a great deal of weight and had noted a gradual increase in the size of her abdomen. She developed a bed sore on the back about four months before entry and had also noticed occasional burning on urination and occasional incontinence of urine.

*Fried, B. M. Chronic pulmonary osteoarthropathy: dyspituitarism as probable cause. *Arch Int Med* 72:565-580, 1943.

Eighteen years before entry she had had all her teeth extracted. For years she had had hemorrhoids, which bled frequently.

Physical examination revealed an emaciated, pale, grossly deformed woman with stertorous breathing and in a clouded mental state. There was bright-red blood about the lips. The tongue was not atrophic, but there were a few varices along the edges. The skin was loose, thin and extremely pale. The scleras were white. There were severe flexion deformities of the joints, all the large joints except the hips being rigidly ankylosed. Fine and moist basal rales were heard over both sides of the chest, and diffuse wheezes over the entire chest posteriorly. The heart was normal. The aortic second sound was greater than the pulmonary. The abdomen was distended and contained a moderate amount of fluid. The liver and spleen were not felt. A deep decubitus ulcer lay over the sacrum.

The temperature was 97°F, the pulse 100, and the respirations 15. The blood pressure was 125 systolic, 65 diastolic.

Examination of the blood showed a red-cell count of 2,300,000, with 7 gm of hemoglobin, and a white-cell count of 11,500, with 95 per cent neutrophils. The urine was acid, with a specific gravity of 1.018, the sediment contained innumerable white cells, an occasional red cell and many bacteria. The stool was liquid and grossly bloody. The serum non-protein nitrogen was 27 mg per 100 cc, the fasting blood sugar 133 mg, the carbon dioxide 21.2 milliequiv per liter, and the prothrombin time 17 seconds (normal, 18 to 20 seconds). A urine culture showed abundant growth of *Proteus vulgaris*.

A whole blood transfusion was begun shortly after admission. At 9:00 a.m. she was responsive and recognized her friends. She had not vomited since admission and showed no other signs of active bleeding. At 3:30 p.m. on the first day the blood pressure had fallen to 80 systolic, 40 diastolic, and the pulse had risen to 130. The skin was cool and clammy, and the patient was disoriented. At about 11:00 p.m. on that day, after a low enema, she passed a large quantity of fresh and clotted blood by rectum. At 9:30 a.m. on the second day the blood pressure had returned to 110 systolic, 70 diastolic, and the pulse was 110. She was in profound coma, and the respirations were stertorous. There were coarse gurgling rales in the dependent part of the chest. The pulse became progressively more rapid and thready. At noon on the second day she vomited dark-red blood. The hemoglobin level at that time was 4 gm per 100 cc. She expired at 3:00 p.m.

DIFFERENTIAL DIAGNOSIS

DR CHESTER M. JONES: We are not favored by x-ray films in this case, and I do not know whether or not that is going to be a help to me. I have been

making notes and juggling figures wondering how I shall bet, but I am definitely far from certain. In regard to the varices, were they said to be telangiectases in the record?

DR BENJAMIN CASTLEMAN Dr Pittman, can you answer that?

DR HELEN S PITTMAN As I recall they were definitely dilated superficial vessels, not telangiectases.

DR JONES I believe that this patient had more than one disease, which is not at all infrequent in this age group. She had obviously had rheumatoid arthritis for many years. Many patients with rheumatoid arthritis are badly nourished, however, as a result of anorexia and loss of weight. Nutritional disturbances, such as hypoproteinemia, prolonged prothrombin time and so forth, are not rare, particularly if salicylates have been given. Furthermore, as our group here has seen, rheumatoid arthritis may be accompanied by changes in the liver, including those of amyloidosis. But it is difficult to see how this could precipitate a picture such as this woman showed. It seems to me that the rheumatoid arthritis is not of primary importance.

The patient gave a six-year story of vomiting, off and on, with two major hemorrhages and a certain number of minor hemorrhages before her final admission. She had no other symptoms of any sort until six months before she entered. At that time she had a different story, namely, one of an increasing loss of appetite and a gradual swelling of the belly, accompanied by marked loss of weight, in other words, there was more weight loss than the scales showed. There was compensation, in a sense, because of an accumulation of fluid in the abdominal cavity. It seems to me that we have to explain the repeated hematemeses and the recent ascites, for both of which we have evidence on physical examination as well as from the story.

What are the causes of vomiting blood from the upper gastrointestinal tract? They are all perfectly well known. It is just a question of which one of these fits the picture, particularly if we try to tie in the ascites. If she had an ulcer, it should have been picked up on one of the previous x-ray examinations. She had had two gastrointestinal series, which at least were said to have been done carefully, — the first one six years before entry, and the second one four years before entry, — and no ulcer was noted. The absence of an ulcer story, together with the failure to find an ulcer by x-ray examination after a careful search, is definite evidence against such a diagnosis, although it does not rule it out. We have had more than one case of a bleeding ulcer that was not found until demonstrated by autopsy or operation, but that is the exception. In these exercises, the proper thing to do is to try to make a logical diagnosis on the basis of the facts presented. I believe that duodenal, gastric or esophageal ulcer is unlikely.

Could she have had esophageal varices, secondary to cirrhosis of the liver and causing bleeding and ascites? If one asks the question that way, of course the answer is that she could have had them, but with such a diagnosis, it would be unusual for her to have lived six years after the first hemorrhage. In the younger age group, we do encounter repeated hemorrhages from esophageal varices due to portal hypertension, the so-called "Banti syndrome", but in the older group, it is unusual to have a six-year interval between the first hemorrhage and the final fatal hemorrhage. I think this is of some importance in an attempt to rule out esophageal varices based on cirrhosis. Incidentally, it looks as if I were talking myself right into a corner. She was x-rayed at another hospital four months before, and if she had had varices they would undoubtedly have been spotted at that time. I assume that nothing was found.

DR CASTLEMAN The only statement that we have with reference to the hospital visit four months ago is that the daughter said that no cause was found for the vomiting of blood.

DR JONES Esophageal varices that cause hemorrhage can occasionally be missed by a careful roentgenologist, but with the six-year story of bleeding it seems rather unlikely that they would have been missed if they had been looked for. At times they are not found simply because the x-ray examination is done in a routine fashion and the esophagus not studied, only the stomach and duodenum being examined as the possible sources of the bleeding. She did not have a palpable spleen or liver, but I think that this may have been because the abdomen was so distended that it was impossible to feel a slightly enlarged spleen or liver. At any rate, for the time being I think that we have to pigeonhole a diagnosis of cirrhosis, but I am sure that it cannot be ruled out.

We have next to consider carcinoma. As a cause of the hemorrhage six years previously this also is an unlikely diagnosis. It is possible, however, that she had carcinoma of the stomach secondary to a benign polyp. We have seen that combination occasionally, but it is an unusual clinical picture. A polyp of the stomach is notoriously silent, and it can be missed by x-ray examination, since it is sometimes difficult to see. Subsequently the polyp may become malignant. Could that account for the ascites? It could, if by that time the patient had a carcinomatous process that had gone through the serosa of the stomach, or if there were regional metastases, either to the lymph nodes or to the liver. So I believe that that has to be put down as a possibility.

Diaphragmatic hernia could perfectly well account for the bleeding, although she had had no symptoms suggestive of diaphragmatic hernia. One sometimes sees fatal hemorrhage from diaphragmatic hernia in old people, but usually there

are symptoms suggesting something around the esophagus or stomach. Furthermore, x-ray films had been taken recently, and they should have shown a diaphragmatic hernia if it had been present. Again, this diagnosis can be missed in routine x-ray studies, but I should think that, if a hernia had been the cause of the hemorrhage, it would have been a fairly large one and would have been noted on x-ray examination.

One thinks of gastritis as a possible cause for this picture, although there were no symptoms. When gastritis is the major cause of hemorrhage, symptoms usually accompany it. With malnutrition, it is not at all surprising to get changes in the gastric mucosa and some atrophy, but this does not imply that such changes were the cause of this patient's bleeding. There is one theoretical reason for gastritis that might be considered, namely, the administration of aspirin. The record states that the patient took an occasional aspirin tablet. If she had been given a dosage of aspirin as large as that frequently employed in this hospital for painful rheumatoid arthritis, one could properly consider the question of gastritis. Fatal hemorrhage from this source has been noted in isolated cases, but it is most unusual to have repeated hemorrhages for six years on the basis of a gastritis due to aspirin. Furthermore, I believe that if this were so there would be a note in the record stating that the patient had taken a lot of aspirin and that it had been discontinued. Symptoms would probably be noted as well. I doubt that the aspirin plays any great role in this case.

If we consider only these five possibilities, we still have no conclusive evidence to help make a diagnosis. There are other conceivable conditions, and I suppose that they might as well be mentioned. She might have had a telangiectasis of the stomach, a curious congenital type of disease that may result in repeated hemorrhages over a long period of time. The telangiectases may be in the mouth, in the gastric mucosa or in any other part of the digestive tract. I take it that the lesions on the tongue were not the type that one gets in multiple telangiectases. I do not believe that she had it.

She could have had abdominal apoplexy, in the sense that one may get massive hemorrhage from a slight erosion that is not caused by a typical peptic ulcer, in which event this hemorrhage may occur anywhere in the gastrointestinal tract and all the x-ray films may be negative. Usually, however, there are a local source of irritation, specific pain and a marked rise in pressure that produces massive hemorrhage. There is no evidence that this patient had hypertension of any degree, so there is no reason to assume that such a thing occurred.

The case boils down, then, to the consideration of ulcer, esophageal varices, cancer on the basis of

preceding polyp, diaphragmatic hernia and gastritis, as the only reasonable possibilities. It is fair to say that the ascites could have been on the basis of nutritional edema. One sees such a picture occasionally, and one is hard put to explain why it occurs only in the abdomen and not in the extremities. We know that the patient had malnutrition. The aspirin may be a red herring. The ascites could have been on the basis of cirrhosis of the liver or on the basis of carcinomatosis, with the primary focus in the stomach or possibly in the duodenum. It seems to me that when forced to choose between such possibilities I am inclined to select cancer on the basis of a previous polyp of the stomach, in large part because of the story of definite loss of appetite of six months' duration, obviously a new symptom for her since she talked about it. Apparently this represented a striking change, something more than rheumatoid arthritis. I believe that this is the most logical bet. If she had cancer, she may or may not have had metastases. She could perfectly well have had fluid in the abdomen due only to malnutrition, although the normal prothrombin time is definitely against it, it is likelier that there were metastases. The other possibilities are cirrhosis with esophageal varices, a silent ulcer and gastritis. I do not see how I can make a more logical explanation. To the best of my knowledge I have never seen ascites associated with a single hemorrhage from ulcer.

DR PITTMAN. We did not believe that it was possible for anyone to make a definite diagnosis on this woman, or at least, I did not believe that it was. She was moribund when she came in, and her daughter added little to the history. I thought, as reported on the record, that a malignant neoplasm was likelier than cirrhosis. The resident bet on cirrhosis with esophageal varices, because he had been impressed with the fact that liver disease does occur in long-standing arthritis.

DR MARIAN W. ROPES. The impression that cirrhosis commonly occurs in arthritis is due to the fact that we recently had several patients with this combination. In general, the only evidence that we have comprises minimal changes in liver function in a fairly large number of cases.

CLINICAL DIAGNOSES

Cancer of stomach
Cirrhosis of liver, with esophageal varices?
Rheumatoid arthritis, chronic

DR JONES'S DIAGNOSES

Carcinoma of stomach, secondary to polyp
Rheumatoid arthritis, chronic

ANATOMICAL DIAGNOSES

Portal cirrhosis of liver, with ruptured esophageal and gastric varices
Hemorrhage into gastrointestinal tract
Ascites
Rheumatoid arthritis, chronic

PATHOLOGICAL DISCUSSION

DR CASTLEMAN The autopsy showed an atrophic, cirrhotic liver, weighing 1000 gm. Microscopically it appeared just like the ordinary garden variety of portal cirrhosis. The process was healed, showing a lot of scarring and surrounding areas of regeneration. The spleen was enlarged, weighing 500 gm. She was a small woman, and probably the reason the spleen could not be felt was that there was 2000 cc of ascitic fluid. The lower three fourths of the esophagus and the first 3 or 4 cm of the stomach

contained huge distended veins, and although we could not find the exact bleeding point at the time of autopsy, which is often the rule because it usually seals over, there is no doubt that a ruptured varix was the source of the hemorrhage. The entire gastrointestinal tract was filled with blood.

DR JONES Which were larger, the esophageal or the gastric veins? The reason I ask is that I am sure that the x-ray examination four months before entry was not a careful one.

DR PITTMAN I do not believe that she ever had a careful x-ray examination. She was terribly bent over and crippled by the arthritis, and it is dubious that she could have had an adequate gastrointestinal x-ray study.

DR JONES We have seen bleeding from gastric varices on few occasions, sometimes due to portal hypertension associated with cirrhosis of the liver or disease of the spleen and splenic vein.

POSTGRADUATE TRAINING OF MEDICAL OFFICERS

DURING 1944, questionnaires requesting information concerning their wishes regarding future medical training were mailed to the approximately 60,000 medical officers on duty with the Army, Navy, Public Health Service and Veterans' Administration. The information contained in the questionnaires returned by 21,029 medical officers is analyzed in the final report,* and the resulting figures present a challenge to all organizations that are considering programs designed to meet the educational requirements of the discharged medical officer. Further-

more, the analysis indicates that certification by a specialty board is the ultimate goal of the young physician — a trend that may materially alter methods for the practice of medicine in the immediate future.

The percentages of officers expressing a desire for long (six or more months) and short (less than six months) courses of instruction were 59.6 and 21.7, respectively, the remainder stating that they did not want any future training.

The ten most popular subjects for the long courses were, in order of frequency, as follows: surgery, internal medicine, obstetrics and gynecology, general review, psychiatry and neurology, pediatrics, orthopedic surgery, ophthalmology, radiology and otolaryngology. The corresponding topics for the short courses were as follows: internal medicine, surgery, general review, obstetrics and gynecology, pediatrics, otolaryngology, ophthalmology, psychiatry and neurology, radiology and orthopedic surgery.

Sixty-three per cent of the group stated that they wished to become certified specialists, and nearly 16 per cent had already been certified by one of the specialty boards. This is all the more surprising when it is learned that nearly 40 per cent of these medical officers had entered military service from private practice.

If one applies the percentages of those desiring long and short courses of instruction to the approximately 60,000 medical officers on active duty, one obtains the figures of 35,800 and 13,000, respectively. Such numbers are sure to tax, if not overwhelm, any scheme of postgraduate instruction that might be devised. It is possible that the eventual figures will not be so large and that the times of discharge will be so staggered that the full impact will be avoided, but in any case, all agencies concerned with supplying these educational facilities — medical schools, hospitals and national, state and local medical societies — should be actively devising methods to meet the demand. This is particularly imperative because of the shortage of medical-school graduates that is bound to occur within the next few years, owing to the shortsighted regulations regarding deferment.

The fact that nearly 80 per cent of this group of relatively young physicians are either certified or

*Lueuth, H. C. Postgraduate wishes of medical officers. Final report on 21,029 questionnaires. *JAMA* 127:759-770, 1945.

desire to become certified by one of the specialty boards is difficult to evaluate. Certainly the practice of medicine has not reached the point — and probably never will — where 20 per cent of the licensed physicians can care for the ordinary aches and pains of the population, indeed, a reverse of the figures appears to be more accurate. Undoubtedly the need for certified specialists is constantly increasing as the science of medicine advances, but the general practitioner must still serve, particularly in small cities, towns and rural districts, unless, perhaps, medical practice is to be radically altered.

PENICILLIN AND SYPHILIS A WARNING

PENICILLIN has been used in the treatment of syphilis in various stages and has been found effective in clearing up the manifestations of the disease. Stokes,¹ in discussing the treatment of late syphilis with penicillin, states that it produces symptomatic and serologic transformations that are equal if not superior to those obtained by long and arduous procedures with arsenic and heavy metals. Moore² reviews the history of chemotherapy and concludes, "The rapid and safe cure of early syphilis is just around the corner." He qualifies this statement, however, as follows: "How best to use it [penicillin], alone or in combination with other forms of treatment, is as yet undetermined but is under organized nation-wide, governmentally sponsored study, from which definite results may be expected rapidly to emerge." This new form of therapy has spurred investigation into other rapid methods of treatment, employing large and frequent doses of agents heretofore used. Although the reports of results by all these methods are distinctly encouraging it should be remembered that the determination of the ultimate cure of syphilis is a long-range process measured in years rather than in months. The ability of the *Treponema pallidum* to remain dormant for many years and even affect the second generation many years after birth has been demonstrated all too frequently in the past.

With these tragedies in mind it is well to mix a word of caution with enthusiasm for a new method of treatment until the end-results are definitely known. It is therefore of special importance that all

patients treated for syphilis in this interim of determining the proper and infallible method, if such can be found, should be followed up serologically and physically with great care over a period of years. Every returning veteran who has been given penicillin for syphilis should therefore be re-examined from time to time to prevent, so far as possible, the late ravages of the disease in himself and his family.

MASSACHUSETTS MEDICAL SOCIETY

DEATHS

GREENWAY — Major Thomas H. Greenway, A U S, formerly of Three Rivers, died June 23 at the Cushing General Hospital, Framingham. He was in his forty-fifth year.

Dr Greenway received his degree from Tufts College Medical School in 1927 and for a time maintained offices in both Three Rivers and Palmer. He served for a number of years as a member of the board of health and as associate medical examiner for this district. Shortly after entering the Army, in June, 1942, he was sent to the South Pacific as medical officer with an amphibious engineers' unit. At Lae he was named for conspicuous heroism when, after being buried under the debris of a falling building, he dug himself out and continued to direct under enemy fire the care of the wounded. After being hospitalized in Australia for a severe case of malaria, he returned to active duty and, while participating in landing operations in an island invasion, received an injury to his back, which resulted in his return to this country for treatment. He was a member of the staff of the Wing Memorial Hospital, Palmer.

His parents, his widow, two daughters, a son and four sisters survive.

PATTERSON — Alice M. Patterson, M D, of Marblehead, died June 20. She was in her seventy-sixth year.

Dr Patterson received her degree from Tufts College Medical School in 1904.

TRUESDALE — Philemon E. Truesdale, M D, of Fall River, died June 12. He was in his seventy-first year.

Dr Truesdale received his degree from Harvard Medical School in 1898. He joined the medical corps of the United States Army in 1917 and sailed for France with the rank of captain in the Yale Mobile Hospital Unit. In October, 1918, he was promoted to the rank of major. On his return to the United States he was assigned as director of surgery at Camp Devens and honorably discharged on March 15, 1919. He was president of the Bristol South District Medical Society from 1927 to 1928 and a councilor at the time of his death. He was a member of the House of Delegates of the American Medical Association in 1929. In that same year he was awarded a gold medal in the Scientific Exhibit of that Association for an exhibit showing experimental demonstration of the mechanism of transportation of abdominal viscera following rupture of the diaphragm. He was director of the Truesdale Hospital, which he had founded. He was a member of the founders' group of the American Board of Surgery and a member of the American Surgical Association, New England Surgical Society and the American Association for Thoracic Surgery. He was a fellow of the American College of Surgeons.

His widow, three sons and four daughters survive.

MEDICOLEGAL ABSTRACT

Right of Compensation Proof of performance of Christian Science practitioner's services In a recent Vermont case a Christian Science practitioner encountered some difficulty in proving that he had actually performed services for which the plaintiff was claiming compensation. The practitioner was not himself the plaintiff, the suit being brought by the person to whom he had assigned his claim. It appeared that it is a violation of the rules of the Church for a Christian Science practitioner to bring a suit at law to recover for treatments given to a patient.

To the Court it seemed the jury could have found that "the nature of the treatments with which we are here concerned is such that the defendant could have no way of knowing whether they were in fact given him, except what Haskins [the practitioner] stated about that matter. The treatments can be given to a patient when absent as well as when present." The Court stated:

Haskins is the only one who knows whether he did in fact give the treatments in question. Neither the defendant nor anyone else can have any knowledge of this matter except what Haskins states about it. While he testified that he gave the treatments in accordance with the tenets of his church, yet, when asked to explain just what he did in giving such treatment, his answers were evasive, several not responsive and several were contradictory. Repeated efforts by the defendant's counsel failed to get any clear cut or definite statement as to just what he did in the giving of such treatment except that such treatment was some form of prayer. Neither could it be learned from him how long such treatments took or just when he claimed he gave them. Such uncorroborated testimony is not of a character to compel a verdict for the plaintiff."

The Court's opinion makes it perfectly clear that the decision is not to be construed as denying the right of a Christian Science practitioner to recover for treatments actually given. It does not go so far even as holding that the evidence required the jury to find against the practitioner, but goes only so far as holding that the jury was reasonable in doing so. The opinion, however, may possibly be interpreted as holding that a jury is always free to disbelieve the testimony of the practitioner that he gave the treatments unless it is corroborated by the testimony of someone else to the same effect. And if this is the correct interpretation, the claim of a practitioner for compensation for treatments given when neither the patient nor anyone else was present is a somewhat precarious claim — (*Kennedy v Williams*, 114 Vt 54, 39 Atl 2nd 193 [1944])

CORRESPONDENCE

DIETS

To the Editor It is 11 p.m., my four young ones are in bed, and my husband at the hospital, so I have finally had a minute to pick up the *Journal*, which came this noon, and, praises be, I finally have an answer for the people who dis-

prove of the way we feed our children. My husband has said ever since we had the first that accepted child feeding is full of "pedigreed bunk," but try to convince a mother or a neighbor who thinks that you are not feeding your babies "scientifically"! I feel like framing your editorial "The Case against Fried Foods." It was only today that I thought of writing a medical magazine to ask, What is the difference between fish fried in fat and fish broiled with fat brushed on it? Our children have eaten from the family table from a very early age, to the horror of most beholders and they are a fine healthy crew. However, since many well meaning interlopers prefer quoted authority to the evidence of their eyes, I am delighted to have something to quote. Thank you for easing the life of a harassed and busy mother. Now if I could only convince my mother that a small piece of home-made fruit cake is no worse for a child than, say, a slice of raisin bread, a few nuts and a piece of plain cake, eaten separately at the same meal, I would be all set.

ALISON BARSTOW MATHERS
(Mrs. Frank P. Mathews)

Vashon, Washington

* * *

The *Journal* always welcomes any criticism of its editorial policies, particularly if the criticism is couched in terms of praise. We, too, have our vanities. Liberal as our policies are, however, even to the point of radicalism, we would not have our readers believe that we have entirely abandoned the idea of certain diets being suitable for children, and others, in a mild sense, for their parents. As Boswell said, "Claret is the liquor for boys, port for men, but he who aspires to be a hero must drink brandy." — Ed

BOOK REVIEWS

Trichinosis By Sylvester E. Gould, M.D., D.Sc. 8°, cloth 356 pp., with 128 illustrations. Springfield, Illinois: Charles C. Thomas, 1945. \$5.00.

This book is essentially a digest of the important publications on trichinosis from its earliest history to, and including 1943. The subject matter is well organized, and the illustrations, most of which are photomicrographs, are excellent. Dr. Gould has produced the best monograph on trichinosis since that of Stäubli written in 1909.

Surgery of the Hand By Sterling Bunnell, M.D. 4°, cloth 734 pp., with 597 illustrations. Philadelphia: J. B. Lippincott Company, 1944. \$12.00.

"Trauma involves all types of tissue, irrespective of the artificial divisions of our specialties. The surgeon must face the situation and equip himself to handle any and all of the tissues in a limb." This quotation from the preface underlies the high aim that the author has set himself in writing this excellent book, and it should be said that he has achieved his objective in a remarkable manner.

The book is divided into four parts. The first deals interestingly with the phylogeny and comparative anatomy of the hand and then proceeds to a discussion of the normal hand from the point of view of the skin, movements, mechanics of muscle and tendon, surgical anatomy, ossification and skeletal maturation. The second is a profitable account of the reconstruction of the hand, its examination, principles and operative technique as applied to problems of the skin and flexion contractures, bones, joints, nerves, tendons and muscles and concludes with a chapter on the arm in its relation to the hand. The third takes up in detail the question of injuries, infections and concludes with a vital discussion of the hand in industry. Finally, the fourth presents a succinct account of congenital deformities, vasomotor and trophic conditions and tumors of the hand.

This excellent book is particularly enhanced in its usefulness by the introduction of nearly six hundred beautiful illustrations. The references are timely and adequate, and one finds a good index. There is no doubt that every library will have this splendid book on its shelf, but it is urged that student interns and surgeons purchase their own copies.

ANESTHESIA BY COMBINED INTRAVENOUS PENTOTHAL SODIUM AND LOCAL NERVE BLOCK*

JAMES C McCANN, M D, Ph D (SURG)†

WORCESTER, MASSACHUSETTS

ANESTHESIA and anesthetic methods have properly concerned the surgical profession as its technical procedures have been perfected. Without adequate anesthesia, an otherwise ideal technical procedure is a matter of trial to the surgeon and a physiologic burden to the patient. Yet the acceptance of anesthetic methods by the surgeon for application to his patients reveals a curious picture of diversity and sectionalism. As far back as 1922 an editorial in the *Lancet*¹ posed this unanswered query "It would be interesting to ascertain why it is that in England and America general anesthesia has been developed at the expense of local, while on the Continent the reverse process has taken place." Gorth,² in reporting a clinical trip abroad for the study of anesthetic methods, as late as 1938 made the following interesting observations:

Anesthesia on the Continent has lagged behind anesthesia in the United States. Recently, however, a large number of Continental clinics are using intravenous anesthesia extensively not only for minor and short operations, but for all kinds of surgery. However, it may be that they are really setting the pace for us rather than going off at a tangent as it now appears. With modifications, then, such as the use of Pentothal during the induction of the splanchnic block, it seems we might perhaps do well to follow Finsterer in our handling of upper-abdominal surgery.

In America there is now a distinct sectionalism in the use of intravenous Pentothal Sodium for major surgical procedures. Reports from some sections indicate marked enthusiasm for its employment for all types of surgical cases, of whatever magnitude. These reports seem at times to lack careful and forthright reporting of the dangers of this method of anesthesia when incautiously administered. On the other hand, probably more frequently in discussion than in writing, one encounters in other sections quite arbitrary and dog-

matic criticism of what is clearly becoming a valuable addition to the methods of anesthesia.

Having carried out short operations under intravenous Pentothal Sodium administered by the syringe method for several years, I and members of the Anesthesia Department at St. Vincent Hospital developed an interest in the use of Pentothal Sodium for major surgical procedures. The approach was based on a systematic attempt to combine intravenous Pentothal Sodium and regional nerve block in a complementary fashion, whereby each would compensate for the inadequacies and undesirable features of the other. After a year of work with this method, it has been brought to such a satisfactory state that in all age groups and in all general surgical cases, except the few enumerated below, it has become entirely the anesthesia of choice for major as well as minor surgical operations. The exceptions are operations in children under seven or eight years of age, because of the small caliber of the veins, operations about the neck, in the absence of intratracheal intubation, because of the too easy stimulation of reflex laryngospasm, operations on patients over sixty years of age who are to undergo a prolonged operative procedure, because of the unsatisfactory metabolic destruction of large doses of the drug and the danger of pulmonary edema from prolonged depression, operations on patients with vomiting, asthma or abdominal distention.

The degree to which combined intravenous Pentothal Sodium and local nerve block has become in our hands the anesthetic of choice for general surgery (excluding its orthopedic branch) is indicated by the selection of anesthesia for the last 784 cases operated on by me during the past year. Local anesthesia was used in 95 cases, spinal anesthesia in 96, inhalation anesthesia (nitrous oxide or cyclopropane or ether) in 80, Pentothal Sodium by syringe in 124 and continuous-drip Pentothal Sodium with local nerve block in 389 cases. Thus, intravenous Pentothal Sodium was

*Read by title at the annual meeting of the New England Surgical Society, Boston, September 20, 1944.

†Surgeon St. Vincent Hospital Worcester.

the major anesthetic agent in 64 per cent of approximately 800 surgical cases of all types. The other agents were each used in about 10 per cent of the cases.

It is becoming generally recognized that intravenous Pentothal Sodium as the sole anesthetic agent does not provide adequate muscular relaxation in an acceptably high percentage of cases, unless used in an excessive quantity that encroaches on the danger zone of respiratory depression. This has led to a search for satisfactory combinations with other methods to provide a satisfactory and safe anesthesia. It is well recognized that supplemental administration of extremely small amounts of cyclopropane or ether quickly and completely takes up the deficiencies of Pentothal Sodium with respect to relaxation. Many surgeons have reported the supplemental use of nitrous oxide and oxygen with this drug, but in our hands it was not found to afford additional help at all comparable with the results procured by the complementary use of regional nerve block. In the few cases in which this combination failed to provide sufficient relaxation of the accessory muscles of respiration to permit easy closure of the peritoneum, nitrous oxide and oxygen did not produce an iota more of relaxation. The deficiency was quickly taken up by a small amount of cyclopropane or nitrous oxide and ether. This situation arose in only 3 or 4 per cent of the cases. No supplemental anesthesia was needed in the rest. Interrupted oxygen administration was carried out, however, when there was the least suggestion of cyanosis, in all cases of anemia, in all prolonged cases and in elderly patients who undoubtedly had some arteriosclerosis or myocardial changes.

Recent reports on the use of curare, a short-acting drug that paralyzes the myoneural junction of skeletal muscles, to produce relaxation is of interest, although its total systemic action indicates caution in its use until it has been thoroughly investigated.

In this series, Pentothal Sodium was administered in a 1 per cent solution by the continuous-drip method, which has been well described in the literature. In the infrequent cases in which the veins were so small as to cause an unsatisfactory rate of flow, a 2 per cent solution was used. After induction, the drug was administered during the period of maintenance in repeated and grouped subminimal fractions of either 5-cc or 10-cc amounts, depending on the rate of metabolic destruction of the drug in the given case. Between each subminimal fraction there was a wait of one minute to observe its effect on the respiratory center. The drug was given from the usual intravenous-infusion apparatus, with the drops regulated through a Murphy drip to about 250 drops per minute for induction and to about 130 to 140 per minute for maintenance. A companion infusion

apparatus provided for continuous administration of saline or glucose solution during the intervals between the groups of Pentothal Sodium fractions, and for the instantaneous administration of plasma or blood without disturbing the patient during the operation. The intervals between fractions were five to fifteen minutes. Having observed the syringe technic for several years, we adopted the above method as the simplest, most dependable and most flexible way of administering Pentothal Sodium.

Local anesthesia — by 1 per cent novocain — was used to take up the deficiencies of the Pentothal Sodium. In the rare cases in which skin sensibility was of so high an order that it was not readily obliterated with the usual quantities of Pentothal Sodium, quick infiltration of the line of incision with novocain permitted this barrier to be easily passed. Relaxation of the rectus muscle comparable to that of spinal anesthesia was procured by direct block of the intercostal nerves in the rectus sheath. Patterns of blocking the sympathetic or intercostal nerves according to the type of operation were mapped out from the background of general experience with regional anesthesia.

In major abdominal operations, Pentothal Sodium alone was capable of controlling all reflexes arising from ordinary manipulations within the peritoneal cavity. Deep reflexes, however, which are elicited by traction on the viscera or their mesenteries, and whose control would have required deep planes of Pentothal Sodium anesthesia, were eliminated by blocking the sympathetic pathways with novocain. This was accomplished in the upper abdomen by anterior splanchnic block, in operations on the bowel by mesenteric block and in pelvic operations by block of the ganglions and sympathetic nerves involved.

This complementary use of the two agents provided a completely satisfactory anesthesia, comparable in all respects, and superior in many, to spinal or deep general anesthesia. It was accomplished with the administration of only moderate doses of Pentothal Sodium. If the two methods are effectively combined, the result provides a speedy, safe type of anesthesia, with an induction and recovery experience strikingly freer of unpleasant and uncomfortable episodes than is the case with the other principal anesthetic methods. Nausea and vomiting are infrequent, postoperative catheterization of male patients is rarely necessary, and in cases of herniorrhaphy has practically disappeared, postoperative headache does not occur, the administration of parenteral fluid, except as required by the technical exigencies of the operation, is reduced almost to the vanishing point, and early ambulation is favored.

Particular consideration should be given to the question of anterior splanchnic block. The method of choice for upper abdominal operations on the Continent, it has found but limited favor in America.

Finsterer and Thorek³ and de Takats⁴ in particular have used it in America. Combined with skillfully administered Pentothal Sodium anesthesia and rectus block, it constitutes an ideal anesthetic method for all operations on the stomach, spleen, gall bladder and ducts. The patient sleeps throughout the operation, there is complete flaccid paralysis of the rectus muscles, there is no reflex stimulation of the respiratory center from traction on the mesentery of the stomach or gall bladder, there is free delivery of the organs up into the incision, there is controllable respiratory quietude, there is never retching, nausea or vomiting, there is very rarely any drop in blood pressure, the pulse does not usually rise, and rarely passes 100, the patient can be maintained in an extremely light plane of Pentothal Sodium anesthesia, there is comfortable and not too delayed recovery from the anesthesia, and instantaneous operative support by the administration of plasma or blood is available as well as continuous saline or glucose infusion, without other disturbing manipulations. Little more can be asked to classify an anesthesia as nearly ideal.

In 1918, Kappis⁵ first published detailed reports of 200 cases operated on under posterior splanchnic anesthesia by the paravertebral approach. In the same year, Wendling⁶ suggested blind penetration of the unopened abdominal wall with a long needle at the level of the first lumbar vertebra to produce splanchnic anesthesia, but of course such a suggestion was never seriously considered. In 1919, Braun⁷ reported the use of anterior splanchnic block by way of the opened abdomen. Finsterer has been an ardent advocate and practitioner of the method, as have been many German surgeons. In 1926 he and Thorek³ reported 2373 cases collected from the literature and personal communications from several German surgeons without a single anesthetic fatality, they were unable to find a single death from this method up to 1936.

The use of splanchnic anesthesia in this series has controlled the strong reflex stimulation of the respiratory center from traction on the subdiaphragmatic mesenteries, the activation of which leads to a high rate of utilization of Pentothal Sodium. During anesthesia from this drug alone these deep powerful reflexes make surgery difficult as a result of extreme activation of the muscles of respiration, particularly the lateral abdominal muscle and the diaphragm. Large doses of Pentothal Sodium administered to suppress this forced breathing activity encroached on the zone of respiratory depression to such an extent that in a few cases transient apnea was encountered. Splanchnic anesthesia controls these undesirable restrictions on the use of Pentothal Sodium, and provides abdominal quietude, adequate relaxation of the accessory muscles involved in the stimulated breathing and minimal excursions of the diaphragm. These effects result in a reduction of about 1 gm in the

average total dosage of Pentothal Sodium required. This is illustrated by two series of cholecystectomies, each comprising 22 cases. In the first series, in which Pentothal Sodium and rectus block were used, the average dose of the drug was 2.19 gm, in the second series, in which splanchnic block was added, the average dose was 1.23 gm.

It will be appropriate to report a modified technic for anterior splanchnic block, based on a special splanchnic needle guide that I devised (Fig 1).

FIGURE 1 Splanchnic Needle Guide

The modification and the guide convert a moderately difficult technical procedure, particularly in the obese abdomen, into a relatively simple and safe procedure. With this modification the procedure was carried out with ease in a deep-chested, obese patient weighing 235 pounds. The purpose of anterior splanchnic block is to deposit an anesthetizing dose of novocain retroperitoneally at the level of the first and second lumbar vertebrae between the aorta and the inferior vena cava. This is an isthmus point or meeting place for all sympathetic nerves and plexuses deriving from the greater and lesser splanchnic nerves and the sympathetic trunks, which supply the stomach, duodenum, pancreas and transverse colon. In the usual technic the finger is pressed downward above the lesser curvature of the stomach and cephalad to the upper border of the pancreas as well as the celiac axis, until it encounters the body of the first lumbar vertebra. In so doing it carries the lesser omentum in the hilus region of the liver down under it, so that resistance and intervening vague fatty tissues confuse the certainty with which the tip of the finger contacts the vertebra and keeps free from underlying structures. The aorta is identified on the right side of the fingertip, and by pressing the aorta to the patient's left and pressing firmly on the vertebral body, the aorta is safely separated from the inferior vena cava. The novocain needle is then inserted directly over the tip of the finger until it distinctly contacts the body of the first lumbar vertebra, when the novocain is injected. The technic may be decidedly difficult in an extremely or even a moderately obese patient. There is a distinctly blind aspect to this technic.

My modified technic makes the procedure certain, safe, easy and exact. With the patient satisfactorily

anesthetized with Pentothal Sodium, two broad-bladed retractors are placed under the left and the adjacent portion of the right lobe of the liver, retracting them upward. A pack is placed along the lesser curvature and over the anterior surface of the stomach so that the left hand can retract it downward, tensing the lesser omentum, particularly where it enters the hilus of the liver. Lateral pressure to the patient's left by the index finger over the corner of the pack carries the fundus of the stomach outward and improves exposure. About in the midline the caudate lobe of the liver is nearly always identified behind the lesser omentum, where the omentum passes between the left lobe of the liver and the caudate lobe. The caudate lobe has a purplish-brown appearance behind the thin screen of the omentum. With the omentum still tensed by downward traction of the left hand, a vertical rent is established in this avascular lesser omentum by an instrument, directly over the tip of the caudate lobe. This permits the caudate lobe to move forward into the rent so that its tip presents in front of the omentum. Usually this area is free of fat and completely avascular, although an occasional vessel may traverse the area. In extremely thin persons nothing is gained by opening the omentum. The tip of the middle finger of the left hand is then advanced cautiously through the rent into the lesser omental bursa, until it comes into direct contact with the body of the first lumbar vertebra. There are now no obscuring membranes between the finger tip and the bone. The pulsating aorta is identified above the celiac artery and the upper border of the pancreas.

The finger and hand are then withdrawn. The splanchnic needle guide is fitted over the second and third phalanges of the middle finger of the left hand. The left hand is again placed in its previous position of retraction over the stomach, again advancing the middle finger, this time bearing the splanchnic needle guide, under the caudate lobe and into the lesser omental cavity, until it again contacts the first lumbar vertebra as a distinct bony structure with no intervening membranes. Pressure firmly applied to the patient's left against the pulsing aorta and downward against the bone safely separates the aorta from the inferior vena cava. A strong 15-cm 18-gauge needle, attached

to a novocain syringe, is inserted in the proximal opening of the small needle guide, through which it is easily and accurately advanced until it impinges abruptly and definitely on the first lumbar vertebra, directly over the tip of the nail of the middle finger, and separated from it by a few millimeters. If desired, the splanchnic guide may be slightly rotated so that the needle can advance a fraction to the right or the left of the middle of the finger tip, according to the dictates of the underlying anatomy of the aorta.

When firm contact by the needle point against the body of the vertebra has been established, 20 cc of a 0.5 per cent novocain solution is injected. During a long operation 10 cc may be repeated hourly. Almost immediately respiratory quietude and relaxation pervade the whole subdiaphragmatic region, with complete obliteration of the disturbing reflex stimulation of respiration previously evoked by traction on the upper abdominal viscera or their mesenteries.

SUMMARY

A brief preliminary report is presented concerning a satisfactory experience during the past year in using intravenous Pentothal Sodium anesthesia with regional nerve block for major surgical procedures in a complementary fashion.

A modified technic for anterior splanchnic block anesthesia, based on the use of a needle guide improvised for accurately carrying the splanchnic needle to assured and safe contact with the first lumbar vertebra, is presented.

Following rather extensive experience with this method, a search was made in the literature for the report of a device like the above-described splanchnic needle guide. Only one brief note was found. Burke⁸ used the same basic principle. He attached a flexible ring to the end of a long grooved director and used the director to guide the splanchnic needle.

DEATH FROM SULFADIAZINE WITH AGRANULOCYTOSIS, JAUNDICE AND HEPATOSIS

Report of a Case

LIEUTENANT COLONEL HROLFE R ZIEGLER, MC, AUS,
LIEUTENANT COLONEL JAMES N PATTERSON, MC, AUS,
AND CAPTAIN WILLIAM A JOHNSON, MC, AUS

THE occurrence of various types of toxic reactions to the sulfonamides is now common knowledge, and all have been fully described in the medical literature¹⁻⁵ in recent years. There have been reported a sufficient number of severe reactions producing death to make the medical profession fully conscious of this danger and of its obligations in this respect. Reactions from the newer compounds have been fewer than those from the older ones. Thus, those seen following the use of sulfathiazole are much less frequent than are those from sulfanilamide, and those resulting from sulfadiazine appear to be still fewer in number. Although agranulocytosis and focal necrosis of the liver have been seen as manifestations of toxicity due to sulfathiazole administration, we, who are not in a position to make a thorough search of the current literature, are not familiar with any report of agranulocytosis and liver damage following the use of sulfadiazine. Simon¹ in a comprehensive review of the pathologic lesions seen in both animals and man states that the most extensive and widespread types of focal necrosis of the liver are seen in deaths following sulfathiazole therapy, but does not mention similar lesions resulting from sulfadiazine. The following case of death after sulfadiazine administration is cited as one believed to have resulted from agranulocytosis and jaundice, in which there was a diffuse hepatitis of moderate degree and marked congestion and early central necrosis of the liver.

CASE REPORT

The patient, a 23-year-old man, had been ill with abdominal pain for 72 hours prior to admission to a regional station hospital of the Army Air Force in Florida. He had previously been in good health and could recall no previous illnesses of any account. He was closely questioned regarding any previous administration of the sulfonamide drugs and was positive that none had ever been given. The history was typical of acute appendicitis, with generalized abdominal pain that had persisted for 24 hours, followed by pain in the right lower quadrant for 48 hours. It was unaccompanied by nausea, vomiting, chills, fever or urinary complaints, and there had been no bowel movement for 3 days.

Examination of the abdomen on admission revealed it to be flat and without distention, muscle spasm or the presence of a mass. Localized tenderness was present in the right iliac fossa, but rectal examination revealed no tenderness or induration. The white-cell count was 10,250, the pulse 100, and the temperature 101.2°F. The policy in this hospital was not to subject any patient to operation for appendectomy if it was thought that perforation of the appendix had occurred but rather to treat such cases conservatively. This case, however, did not suggest perforation, and the patient was operated on under spinal anesthesia within a few hours of admission. When the peritoneum was opened through a McBurney incision, foul-smelling, cloudy fluid was encountered, from which a paracolon bacillus was cultured. The appendix was adherent to the cecum, the wall of which was markedly in-

durated. Inasmuch as attempted removal of the appendix would have been extremely difficult the operation was concluded by placing 10 gm of sulfanilamide in the peritoneal cavity in the region of the appendix and closing the wound in layers around a cigarette drain.

Postoperative treatment consisted of constant Wangensteen suction supportive therapy with adequate fluid intake intravenously, morphine, nothing by mouth and 5 gm of sodium sulfadiazine administered in two doses daily by the intravenous route (Fig 1). The course was somewhat stormy for 9 days, during which time the temperature fluctuated in the neighborhood of 102°F and the pulse around 100 per minute. Considerable distention developed in spite of the continuous gastric suction and on the 8th postoperative day this had reached such proportions that it was thought advisable to pass a Miller-Abbott tube. This was successfully passed into the duodenum, whence it rapidly traveled to the lower ileum and decompressed the abdomen completely within 12 hours. The temperature was normal on the 9th day, intestinal suction being discontinued on the 12th day. Intravenous sulfadiazine was discontinued on the 11th postoperative day, and thereafter was given in 2-gm daily doses by mouth until the 18th day.

During this entire interval the blood chemical findings and cell counts were satisfactory, and although the wound continued to discharge a moderate amount of pus, the patient appeared to be making a satisfactory recovery after the 12th day.

On the 16th postoperative day, the temperature reached 100°F, and increased daily so that by the 21st day it had reached 104°. The distention did not recur, and repeated examinations of the abdomen and rectum revealed no evidence of a recurrence of abscess formation. Fluoroscopic and x-ray studies of the diaphragm and chest were normal. Two days after the onset of this fever the daily 2-gm dose of sulfadiazine was discontinued in the belief that this might have accounted for the febrile reaction, but the temperature continued to rise for 4 more days. The white-cell count which was 9000 when the drug was discontinued, dropped to 4000 on the following day, but rose to 5900 on the 21st day. The possibility of pyelphlebitis and multiple liver abscesses as a cause for the fever was entertained, but there was no evidence of icterus or ascites of even mild degree. On the 22nd day of the illness, it was believed that there was some increased induration in the region of the wound that might possibly account for the recurrence of fever, and a second operation was therefore undertaken.

Under intravenous Pentothal Sodium anesthesia the original wound was explored with the finger. Although it was unhealthy in appearance, no abscess pockets were encountered, and the operation was concluded in 10 minutes. While the patient was on the operating table there again was considerable discussion by members of the staff concerning the cause of the fever. Pyelphlebitis with multiple liver abscesses was again considered. Several medical officers inspected the scleras in a good light for evidence of an early jaundice, but none was seen.

Within 2 hours after the operation several dramatic incidents occurred. First, the patient developed cyanosis, which was rapidly and successfully treated with oxygen and intravenous caffeine sodium benzoate. During this time he was receiving 2.5 gm of sodium sulfadiazine intravenously. Within 1 hour marked jaundice suddenly developed, and blood studies revealed an icteric index of 106 (van den Bergh, 38 mg per 100 cc.), and the startling fact that the white-cell count had dropped to 450. Blood smears at that time revealed a total absence of granulocytes. These untoward developments were accompanied by a rise in temperature to 106°F and an increase in the pulse to 130.

For the next 5 days, the condition of the patient was critical, with the temperature fluctuating between 104° and 106°F and the pulse between 130 and 160. The jaundice increased,

the icteric index reaching 177 on the 3rd postoperative day. Although the serum protein level was above 6 gm per 100 cc, the albumin-globulin ratio dropped to 1:1. All the other blood findings, including the nonprotein nitrogen, blood phosphatase, chloride, hemoglobin and red-cell count, remained within normal limits. General supportive measures were undertaken, including the adequate administration of fluids, continuous oxygen and transfusion of 1000 cc of fresh compatible citrated blood daily. These procedures were of no avail, although the white-cell count did rise to 2450 and 2000 on the 3rd and 4th postoperative days. The smears, however, continued to show an absence of granulocytes in the blood, and the patient expired on the 5th day after the second operation, 26 days after admission.

Autopsy. Autopsy was started within 1 hour after death. The body showed evidence of considerable weight loss. The

The lower edge of the liver was 1 fingerbreadth below the right costal margin, the left lobe extending to the left anterior axillary line. The common bile duct and the hepatic duct and its large branches were opened upward from the ampulla of Vater, but no obstruction or stone was noted. The cystic duct showed no abnormalities. The wall of the gall bladder was not thickened and contained no stones. On section of the liver the edges everted markedly. The liver was reddish brown and on close inspection had a nutmeg appearance. The entire liver was sectioned into thin slices and presented the same picture throughout. The consistence of the organ was not changed to any appreciable extent.

The spleen was dark reddish blue and approximately three times its normal size. It was firm and retained its shape on removal from the body. The mucosa of the cecum was reddened, granular and swollen. The kidneys were swollen and

FIGURE 1

skin and conjunctivas were markedly icteric. Two cigarette drains were present in the recent McBurney's incision, along which was noted a small amount of foul-smelling, purulent-looking material. The greater omentum was pulled to the right and was held by thick fibrinous adhesions to the peritoneal lining of the right lower quadrant of the abdomen, thus walling off this area. The peritoneal cavity was otherwise unaffected except for approximately 5 cc of purulent-looking material walled off by thick fibrinous adhesions in the rectovesical space. The distal half of the appendix had been eaten away, and the wall of the stump was slightly thickened, and its serosa granular and reddened. The small tributaries of the superior mesenteric vein draining the terminal ileum, cecum and appendix were cross-sectioned approximately every centimeter of their distance and found to be patent, as were the arteries. The superior mesenteric and portal veins were opened throughout their length, but no thrombi or break in the intimal lining was observed. The regional lymph nodes were markedly enlarged, grayish yellow and fairly firm in consistence.

The edges everted on section. The cortex of each kidney was pasty yellow and was moderately widened. The medulla were injected. The capsules stripped with ease, leaving smooth, even surfaces. The suprarenal glands were of normal size but were slightly softer than normal.

The lungs showed no abnormalities other than for congestion and edema in the most dependent portions. The pleural cavities were free of adhesions. The pericardial cavity contained approximately 50 cc of bile-stained watery fluid. The pericardial lining was smooth and glistening throughout. The heart was flabby and did not retain its shape on removal from the body, the musculature being brownish red and soft. The coronary vessels were patent throughout, and the valves were not thickened. The intima of the first part of the aorta contained an occasional atheromatous plaque. The lining of the aorta had a yellowish tint, as did many other tissues throughout the body.

The bone marrow of the sternum and ribs was hypoplastic. Smears from sternal bone marrow showed a hyperplasia of immature myeloid elements with an apparent arrest of maturation.

tion at the myeloblastic level. Most of the cells appeared to be myeloblasts, containing from two to three nucleoli.*

Microscopical study of the tissue revealed less damage to the liver cells than had been expected from the deep jaundice. The central veins were engorged, with resulting atrophy and early focal necrosis of the adjacent liver cells. Fat stains revealed focal areas of fatty degeneration of the liver cells, which were more marked in the central areas. The remainder of the liver cells showed swelling, increased granularity and bile retention, but otherwise they were fairly well preserved. Study of many sections failed to reveal any evidence of obstructive dilatation of the intrahepatic bile ducts, which substantiated the autopsy finding of no obstruction of the large bile ducts. There was no histologic evidence of previous liver damage (this is often present in persons showing liver disease from sulfonamide drugs).

The appendix showed a subserosal zone of necrosis with bacterial colonization and with practically no cellular reaction. The reaction of the mesentery to the peritonitis was practically exclusively plasmocytic and lymphocytic, with an interspersed occasional macrophage and histiocyte. If only sections showing the reaction to the peritonitis had been seen, one would of necessity have considered seriously the rare entity of aleukemic plasma-cell leukemia.

Microscopical examination of the spleen revealed marked depletion of nucleated elements of both follicles and pulp. The kidneys showed normal glomeruli and cloudy swelling of the tubules. Many bile casts and an occasional hemoglobin cast were found.

A blood culture taken at the time of the post-mortem examination and grown on tryptose phosphate broth and heart-infusion broth showed a gram-positive rod, a gram-negative rod and a gram-positive coccus. This finding had little significance, since blood cultures taken a few days after the second operation and planted on the same mediums were still sterile after 21 days of incubation.

The points to be stressed in the progress of this patient are as follows. Up to the sixteenth post-operative day he was apparently making a satisfactory recovery from incision and drainage of a local peritonitis due to perforation of the appendix. Fever then recurred to an increasing degree daily, and four days after sulfadiazine therapy was discontinued the fever continued to rise, reaching a maximum of 104°F. Following the second operation a short period of anoxia occurred during the administration of 2.5 gm of sodium sulfadiazine intravenously. Sudden and rapid onset of jaundice,

*All these findings were confirmed by Dr Roy R. Kracke of Emory University.

accompanied by a marked leukopenia and agranulocytosis, occurred within one hour of administration of the sulfadiazine. Lastly, post-mortem examination showed no evidence of infection to account for the fatal termination, but did reveal a hyperplasia of immature myeloid elements, with an apparent arrest of maturation at the myeloblastic level in the bone marrow, and enlargement of the liver due to a diffuse hepatosis with early central focal necrosis. Histologic examination of the liver failed to give a completely satisfactory explanation for the intense jaundice.

In retrospect it is believed that the febrile reaction occurring from the sixteenth to the twenty-second postoperative day was a toxic reaction to sulfadiazine, the patient having received 71.5 gm of the drug up to the eighteenth day. It is further considered that the sudden development of jaundice and agranulocytosis after a further administration of 2.5 gm of sulfadiazine probably produced an exacerbation of the hypersensitiveness to sulfadiazine, with the resultant liver and bone-marrow changes that led to the fatal outcome.

SUMMARY

A fatal case following the administration of sulfadiazine and presumably due to toxic damage of the liver and bone marrow is described, and the post-mortem findings are discussed.

TUMOR OF THE CAROTID BODY*

HORACE K. SOWLES, M.D.†

— BOSTON

THERE is nothing new to be said in regard to tumors of the carotid body. The only excuse for presenting this subject to the surgical profession is a plea for a correct preoperative diagnosis. If this is made, it may well be possible to reduce the rather high mortality that has accompanied the surgical cure of this lesion.

The correct diagnosis should not be too difficult provided that one considers carotid-body tumor in the differential diagnosis. The only difficulty has been that this condition is not frequently encountered, and that therefore one fails to give it consideration.

The carotid body was first mentioned by von Haller¹ in 1743, and was described in detail in 1862 by Luschka.² It is a tiny organ about the size of a grain of rice situated at or near the bifurcation of each common carotid artery. It is supposed to reach full development at about the age of twenty, but in some cases it either does not exist or is so tiny that it is not found at autopsy. It is always closely attached to the wall of the carotid artery, but its exact location is not constant.

Embryologically the carotid body is a complex structure of somewhat disputed origin. By some it is supposed to arise from mesodermal tissue of the third branchial cleft and to be somewhat homologous to the medullary portion of the suprarenal gland. By others it is thought to have its origin in the sympathetic nervous system. Certainly it is well supplied with nerve fibers. It is intimately associated with the periarterial sympathetic fibers of the carotid artery, receives fibers from the glossopharyngeal nerve and the upper cervical sympathetic ganglion, and sometimes has a communicating branch with the vagus nerve.

Physiologically it is apparently of no great importance. There is little or no evidence in favor of including it among the glands of internal secretion. The facts that it is sometimes absent and that bilateral extirpation can be carried out without any subsequent symptoms suggest that its function, whatever it may be, is negligible. This being so, the only clinical interest in the carotid body is its pathology, and the only pathologic lesion is a tumor. It is said that the first recorded operation for tumor of the carotid body in America was performed by Middleton³ in 1895. The tumors in general maintain the same histologic characteristics as does the normal carotid body. Definite malignancy

as indicated by active mitosis is found in 50 per cent of the tumors, and all are potentially malignant. Distant metastasis has never been proved, but local recurrence has occurred in 20 per cent of the malignant cases.

The tumors are usually unilateral, but an occasional bilateral involvement has been reported. They manifest themselves as painless, slow-growing tumors situated in the superoanterior cervical triangle, pushing out from under the anterior border of the sternomastoid muscle. They are usually ovoid, firm but elastic and deep seated, and are never attached to the skin. They are extremely vascular. Sometimes a bruit or thrill is present, and often a transmitted pulsation from the carotid arteries is evident, but this is to be differentiated from the expansile pulsation of an aneurysm. Compression of the carotid artery below the tumor abolishes the bruit, thrill or pulsation and sometimes causes a diminution in its size. These tumors usually have some lateral mobility, but possess little or no vertical mobility because of their firm attachment to the carotid artery. This is an important diagnostic point.

Carotid-body tumor is a disease of middle age, the average age of patients being about forty-five years at the time of operation, but some of the tumors have been present from ten to fifteen years, with an average duration of five or six years.

When any other symptoms, aside from slow, painless growth, are present, they are usually caused by invasion or compression of other important regional structures, such as the vagus nerve, the sympathetic or recurrent laryngeal nerves or the pharynx or esophagus. Episodes of fainting, hoarseness, dyspnea, dysphagia, cough, tinnitus or headache have been reported, as has Horner's syndrome from pressure on the cervical sympathetic nerves.

The correct diagnosis of these tumors is rarely made preoperatively—in less than 10 per cent of the reported cases. This is undoubtedly due to the fact that the condition is so rare that its existence is not even considered by the examining physician. Only 20 cases of carotid-body tumor were to be found in the records of the Mayo Clinic in 1941, and somewhat over 200 in the entire medical literature.⁴ The most frequent incorrect diagnoses are tuberculous adenitis, branchial cyst, metastatic carcinoma, aberrant thyroid gland and aneurysm.

If the diagnosis of carotid-body tumor is considered at all, it should not be too difficult to arrive at the correct answer. The most important indica-

*Read by title at the annual meeting of the New England Surgical Society, Boston, September 20, 1944.

†Visiting surgeon, Massachusetts General Hospital; surgeon, Faulkner Hospital; chief of staff, Lawrence Memorial Hospital, Medford.

tion of such a diagnosis is the presence of a slowly growing, painless, deep-seated tumor in the upper anterior neck, particularly if, as before mentioned, there is lateral mobility without vertical mobility, not to mention marked transmitted pulsation, and perhaps diminution in the size of tumor on cutting off the circulation by pressure on the common carotid artery.

The importance of establishing the correct diagnosis before operation is that steps can then be taken to reduce the dangers involved by the operative procedure. The chief danger is death from cerebral anemia or hemiplegia, should sacrifice of the carotid arteries be necessary at the time of excision.

It is generally accepted that surgical removal is the ideal treatment for tumors of the carotid body, particularly if this can be done without sacrifice of the carotid vessels. Some years ago, however, Bevan⁵ expressed the opinion that if the tumor proved to be inoperable without sacrifice of these vessels, the incision should be closed as would be done in any other exploration for inoperable disease, and the patient treated with radium or x-rays. Little is found in the literature, however, to indicate that these tumors can be treated successfully with radiation. There is also some doubt whether it would be possible to go no farther after exploring the tumor sufficiently to determine that the carotid vessels must be sacrificed. At such a point one might well be committed to a completion of the operation to control the bleeding from the extremely vascular tumor. A complete removal of the tumor is indicated even at the additional risk involved because of its malignant or potentially malignant nature.

In a series of 159 cases reviewed by Phelps, Case, and Snyder⁶ in 1937, the mortality rate was 24 per cent. In the series of 20 cases at the Mayo Clinic, reported by Harrington, Clagett and Dockerty⁴ in 1941, the mortality was 20 per cent, in the cases in which ligation of the carotid vessels was necessary it was 44 per cent. The average age of the patients who died following ligation was fifty-three, and that of those who survived it was thirty-one. This indicates an increasing risk with advancing age.

Because of this pronounced danger, particularly in old patients, it seems wise to give every possible preoperative preparation to the patient in whom a tumor of the carotid body is suspected. This preparation should consist of systematic compression of the common carotid artery against the transverse process of the sixth cervical vertebra. This pressure should be carried out for an increasing duration of time, and several times a day, over a period of several weeks if necessary, until the patient can tolerate complete compression of the vessel for long periods without experiencing faintness or loss of consciousness. Linton⁷ has developed a tourniquet

in the form of a rigid collar around the neck, pressure is exerted on the carotid artery by means of a pad activated by a screw. It is hoped by this procedure that the collateral circulation to the brain on the affected side can be improved.

There is some difference of opinion whether collateral circulation in this part of the body can be developed. Possibly in certain cases anatomic variation in the arterial circulation at the base of the brain may prove to be an unsurmountable barrier. Certainly if a patient has a so-called "carotid reflex," — namely, syncope caused by pressure on the carotid artery, — one should hesitate to divide the artery at operation unless the reflex can be abolished by some such development of collateral circulation as is suggested above.

There are of course other structures that may be injured during the operative removal of a carotid-body tumor. Some of these are the internal jugular vein, the vagus nerve, the recurrent laryngeal nerve, the hypoglossal nerve and the cervical sympathetic chain. With care and a proper technic, however, these injuries should be reduced to a minimum, and naturally they are not so serious as a hemiplegia.

The clinical case that brought this subject again to my attention is as follows:

CASE REPORT

M H, a 44-year-old, unmarried woman consulted me on January 18, 1944, because of an unsightly swelling in the right side of her neck. She had first noticed a small lump in this area in 1935. This had gradually increased in size. She had had no pain or discomfort, except for occasional attacks of headache.

Examination revealed a tumor in the upper neck, just anterior to the sternomastoid muscle, 7 cm. in diameter with the vertical dimension slightly longer than the horizontal. It was firm and nontender. There was a definite bruit and pulsation that seemed to come from surrounding vessels and not from the tumor itself. The latter was slightly movable in a lateral direction. There was a vertical scar 5 cm. long over the tumor where a surgeon had attempted several years previously to remove it, but had stopped the operation, explaining to the patient that he was not prepared for such a serious dissection as would be necessary for its removal. I believed that this tumor probably arose from aberrant thyroid tissue and advised operation.

Operation was done under a general anesthesia. Owing to the extreme vascularity of the tumor, every precaution was made to control all small blood vessels, and the dissection was carried out slowly and carefully through an ample incision. The tumor was eventually entirely exposed and seemed to arise from the bifurcation of the carotid artery. It could be dissected from the carotid, however, without damage to that vessel, and the wound was closed. The patient made a comfortable, uneventful recovery, being discharged from the hospital in 4 days. The pathologist reported a tumor of the carotid body, which had not been considered as a possible diagnosis.

SUMMARY

Tumors of the carotid body are rare, but should be considered in all slowly growing, painless tumors of the upper neck, and if considered, the correct diagnosis should be arrived at with reasonable accuracy. Their incidence is the same in both sexes. The majority of patients are between forty and sixty years of age.

These tumors are always either malignant or potentially so. They rarely recur, and almost never metastasize after complete surgical removal.

The operation is delicate and dangerous.

Ligation of the carotid vessels is necessary for complete removal in 50 per cent of the cases.

Preoperative preparation consists of systematic compression of the common carotid artery several times daily for gradually increasing periods until the patient can tolerate complete compression for long periods without syncope.

MEDICAL PROGRESS

PSYCHIATRY: REHABILITATION

VERNON P. WILLIAMS, M.D.*

BOSTON

CURRENT psychiatric literature continues to be composed, in great part, of papers dealing with the psychiatric casualties of war. It is now well established that the earlier treatment is begun the better are the chances for recovery. Of course the same principle applies, and always has applied, to the psychiatric illnesses of peacetime living. So much has been written, both in scientific journals and in the popular press, about war nerves, combat fatigue or psychoneurosis that not only the public but psychiatrists themselves may have lost a well balanced perspective on this subject. Also popular alarm has been augmented by the large number of inductees rejected as "not suited for military service" on the basis of a neuropsychiatric or personality disorder.

Although exact statistics are not available, it is reported^{1,2} fairly consistently that about 45 per cent of the medical discharges from the armed forces are for neuropsychiatric disability. Considering that the men receiving medical discharges to date constitute a small proportion of the grand total of those in service, the problem of the veteran who returns to civilian life with war nerves is not, and will not be, so appalling in extent as the alarmists portray. If qualities of human nature can be spoken of in the sense that human nature is at all responsible for them, it is a compliment to human psychobiologic integration that comparatively so few men become psychiatric casualties under the impact of the terrific conditions of combat.

There is, of course, the problem of rehabilitation for many men who develop nervous disorders during their time in service. Pratt³ states that as of September, 1944, more than 300,000 men had been discharged for psychiatric conditions. Important

considerations in this problem are insufficient facilities for treatment and the reluctance or refusal of numerous men to accept treatment. Even before the war, federal veterans' hospitals were overcrowded and there were less than 3000 psychiatrists in the country.⁴ It may be hoped that the awareness of and interest in nervous or emotional disorders increased and, in many instances, awakened by the present war will be maintained, both by physicians who are not psychiatrists and by laymen.

The aversion of the veteran to seeking psychiatric treatment is not difficult to comprehend. Society has looked askance at psychiatry for generations. Gregg⁴ refers to "the inherent, the inveterate, the inevitable handicaps of psychiatry." He writes, "The three most powerful traditions or historical heritages of psychiatry are still, as they have been from time immemorial, the horror which mental disease inspires, the power and subtlety with which psychiatric symptoms influence human relations, and the tendency of man to think of spirit as not only separable but already separate from body." Another handicap might be included. Neurotic and, to some extent, psychotic illness entails the question of personal responsibility, free will. Again and again the patient ill with neurotic symptoms expresses the wish that some physical cause might be found to explain his disability. At least half-consciously he fears to hear what he partly senses may be true, "It's up to you." Human pride or egotistic desire is such that it is difficult to admit that what is up to one may be more easily accomplished if one permits the doctor to help.

Government facilities for treating the veteran have not been, are not now and will not be adequate. It is well known that the veterans' hospitals have not been able to give satisfactory care and treatment to the casualties of World War I. Suggestions are

*Assistant in psychiatry, Massachusetts General Hospital.

being made that the federal government could contract for the care of veterans with the general hospitals Cunningham⁵ writes "Veterans are best treated in community facilities," thus precluding bureaucratic organization Terhune⁶ states

This problem is too big for the government to handle

If the government tries to care for these patients, after discharge from the Army, results will be unsatisfactory. The practice of medicine is based on an individual relationship existing between doctor and patient — this necessary personal emotional transference cannot exist between a government bureau and patient. Therefore, it will be the job of civilian physicians, who know these men and are familiar with the facilities of the communities in which they live, to readjust them to civilian life

Various writers have commented on the fact that the development of a nervous disorder under the circumstances of military service does not warrant the assumption that the man affected will be unsuited for at least a reasonably adequate adjustment to civilian pursuits Burlingame,⁷ in writing on industrial psychiatry, says

If a person is discharged from the armed forces with the diagnosis of psychoneurotic, it simply means that the individual did not have the necessary adaptability to become a successful employee of the armed forces. This diagnosis carries with it no adverse implication concerning that person's re-employability in industry

It is to be remembered that over a million men have been rejected in this country as not fit for service in the armed forces because of some neuropsychiatric disability. Again, exact statistics are not available, but it is known that the majority of these men were carrying on successfully enough in civilian life

If there is a correct understanding on the part of doctors and the public in general, most of the veterans who are nervous will readjust to life out of the service without great difficulty. Referring to the physician's treatment of the man who has not qualified for service, Terhune⁶ writes

Explain that they were not rejected, they were just not accepted for military duty, that this was for their own protection, and because they could be more useful to the Nation in other lines of endeavor. Reassure them about their own essential fitness for civilian life, pointing out that many of the qualities which make for a successful civilian do not necessarily make for a good soldier

If there exists, as part of man's response to his environment, a normal emotional reaction, — and outside of the psychiatrist's world, at least, it does exist, — then many of the fear and anxiety reactions engendered and precipitated by the indescribable conditions in combat zones cannot justifiably be labeled "psychoneurotic"

Thomas⁸ refers to the injustice of calling all manifestations of fear, anxiety and depression psychoneurotic. In reporting on 4 cases in which there was temporary maladjustment, he writes

They constitute a behavior pattern that has been witnessed in armies throughout the ages. Until the advent of modern psychiatry, such conduct was attributed to a variation in men's capacity to sever themselves from their

usual way of life and to conquer a fear of impending death. The will to fight, morale, training, fatigue, disheartening reverses and leadership were recognized as factors able to influence a man's emotions. These factors are acknowledged in this war, but the frequency with which the diagnosis of a psychoneurosis is made raises a suspicion that psychiatrists have encouraged a shrouding of them in an ill use of terminology. In doing so they have thrown the problem of psychoneurosis out of focus with what seem to be the facts. There are psychiatrists who regard the familiar fear of a soldier in a dangerous situation as a measure of the emotion of an anxiety neurosis. This is tantamount to calling all frightened and bewildered soldiers psychoneurotic. Careless use of the term ["anxiety"] does injustice to the Army, the soldier and the taxpayer

Thomas suggests the use of the term "simple adult maladjustment" when the ramifications of what a diagnosis of psychoneurosis implies are not present. He continues

It is obvious from what has been said that I believe that some of these cases present problems in morale, discipline and stamina. If this is so, it follows that any term connoting a mental disorder will cloud the issue. The answer to the question seems to rest in the prophylactic orientation program now under way — the prevention of states that require a stigmatizing name

This question of nosology is important because people generally are still not well educated in regard to nervous disorders. They forget the wisdom of the Quaker's statement that "Everybody is queer except thee and me, and sometimes I think thee is a little queer." At best the label of psychoneurosis is dangerous because it tends, in the mind of the person so labeled and in the minds of others, to distinguish and to separate him from the rest of the supposedly normal world

The psychiatric casualties of this war may be roughly divided into two groups, those suffered by men whose previous integration has been averagely sound and who have broken down due to intolerable circumstances, and by those whose histories reveal evidence of instability before the beginning of their military service. Prognosis is better for the first group, but it is probable that the second group comprises the larger number of the disabled. Rennie and Woodward⁹ report that of 380 cases seen at the Rehabilitation Clinic of the New York Hospital, 75 to 80 per cent gave a history of difficulty antedating service

The work of rehabilitation is not being left entirely to civilian and Veterans Administration resources. Both the Army and the Navy have already instituted treatment in the directions of both reconditioning and rehabilitation. Braceland,¹⁰ in writing of the Navy's project, says

It is encouraging to know that in this particular field the Navy has had a rehabilitation plan in operation for well over a year. This program has now expanded to such a degree that the basic idea of treatment and reconditioning is operative from the time the individual becomes a neuropsychiatric casualty on some Pacific atoll or island until the time he is considered recovered or is discharged to the Veterans' Administration facilities for further treatment.

Group therapy, according to the same author, is the method of choice

That group therapy is effective is the opinion of Dynes, Hamilton and Cohen.¹¹ They write that, although not all patients are cured, many have left the hospital with an unhostile attitude. They add

Many expressed a feeling that they had been treated fairly and had hopes and plans for the future. This contrasts sharply with those patients discharged from the service who return to their homes in an unhappy frame of mind and immediately become candidates for veterans' aid, instead of making an attempt to help themselves.

In the group discussions, as conducted by Dynes and his associates, the members were encouraged to describe their symptoms. The meaning and nature of symptoms were then discussed in relation to personality and its development, anatomy, physiology, emotions and their influence on mind and body. The authors say that the individual patient was not embarrassed, any particularly sensitive points being discussed privately.

In a description of the process of group therapy in an Army hospital, Paster¹² relates that it is usual for the aggressive, extroverted patient to express himself first.

The timid and the withdrawn then follow with comparative ease. It is remarkable how patients who, when individually interviewed, are reluctant to discuss their terrifying past change their attitude during the group sessions. Surrounded by other patients who manifest symptoms similar to their own, most of them lose their sense of inferiority. They talk much more freely about their painful experiences and reveal the inner turmoil they previously tried to repress.

The value of this therapy is evident in that 85 per cent of the men so treated have been returned to duty, although not as combatants. Part of the value, according to Paster, lies in the patient's finding that he automatically minimizes his personal problems as the latter become a part of the larger group problem. Also the presence of other patients helps to socialize each of them. Paster concludes

The favorable response of the patients to the comparatively brief period of treatment [two or three times a week for four to six weeks] corroborates the opinion of many that psychoneurotic reactions arising in combat are not generally deeply rooted. They do not fundamentally represent lifelong problems, but rather symptoms of acute maladjustment to intolerable situations.

Helpful as group or individual therapy may be to a man while he is still in service, partial or apparently complete restoration to mental or emotional health before discharge does not preclude difficulties in making the transition back to civilian life. The success or efficacy with which this adjustment will be made depends on the individual veteran's plasticity and emotional integration and various factors in the society to which he returns. One of the most important elements in this situation is the matter of compensation or pensions for veterans. Unfortunately, many men will accept government aid as long as it may be forthcoming, and thus neurotic reactions will become fixed either for life or for years.

Sinclair,¹³ of the Australian Army Medical Corps, who has had comprehensive psychiatric experience in the present war, admonishes

The nation is still paying for the neuroses directly or indirectly attributable to the last war. The burden following the present conflict will be far greater. The policy adopted after the last war was to pension the soldier and to treat him at a repatriation centre. It will be a great pity if we repeat that folly. There seems no doubt that to shackle the neurotic to his symptoms and disabilities by a monetary dole is a poor solution to his problem. Society will best support the neurotic repatriated soldier by giving him constructive, creative and sympathetic service, rather than by paying him a fortnightly pension in an endeavor to forget him.

What Terhune⁶ has to say on this subject is worth quoting.

The greatest hazard that exists in treating ex servicemen who are psychoneurotic is that they are eligible for federal pensions. Once these men have applied for a pension or have secured one, it becomes practically impossible to cure them. Few compensation neuroses recover as long as the compensation continues in effect. It is unfortunate that recent federal legislation makes these patients eligible for pensions, since this very fact will make many confirmed neurotics of individuals who would otherwise recover. Such federal provision was made without consultation with medical authorities familiar with the problem.

The author urges medical societies to fight for new legislation. In dealing with the veterans themselves, he advises the doctor to try to persuade them "not to apply for pensions, pointing out the nature of the risk and showing them that by accepting pensions they are selling their birthright of happiness and usefulness, dooming themselves to lifelong discomfort, all for a mere pittance."

The numerous psychologic hurdles standing in the way of the returned soldier's successful reorientation to civilian life have been well presented at length by Pratt.² He discusses the possible obstacles that may be present both in the veteran's attitudes and in those of his family and social milieu. Patience, forbearance and an unremitting attempt to understand are the keynotes for success.

Chisholm,¹⁴ in an excellent paper, outlining the Canadian Army's proposals for preparing its soldiers for demobilization, writes of some of the most important points related to rehabilitation. He says

Aggressive urges which have been carefully nurtured and developed over a period of years are supposed to disappear overnight, leaving a peaceful civilian with no such pressures and consequently no need of outlet. The soldier is expected overnight to give up what in very many cases at least is a consuming hatred and in all cases the object of aggressive antagonism. With the memory of his friends or relatives who have been killed or maimed or even tortured by the enemy, fresh in his experience and kept alive as a spur to his aggressions, this change-over in attitude may be very difficult indeed. It may be successful on the surface but at the expense of extensive repressions and conflict within himself.

The well-known tendency of the soldier at war and the wife at home to idealize each other, with perhaps consequent disillusionment, fears of what may or may not have been infidelity, idealization of the father by the mother to the children, at

variance with the real father on his return, the wife's independence, personally and financially, in relation to her husband, while he has been away, the wife's experience in war work, having broadened her horizon beyond the domestic round, the matter of re-employment or employment for the first time in a civilian job for the returned soldier — all or some of these situations may be the source of difficulties. According to Chisholm, the Canadian Army's plan is an attempt to make the soldier's transition to civilian life less uncomfortable and, as so often happens, disillusioning by courses of lectures and discussions in small groups on all conceivably pertinent subjects.

The working and suffering together and the value of their efforts to their countries have given to many soldiers a well deserved self-esteem that may never have been experienced by them before to such degree. The doffing of the uniform and the return to a position of relative unimportance can be a serious threat to healthy adaptation unless families and the community remember that the wisest form of appreciation goes farther than an initial flag-waving reception. In another paper, Chisholm¹⁵ comments on this

For some years the soldier will have been accustomed to regarding himself as important, as a great asset to his country and as highly valued by his associates. The most damaging thing that could happen to the returned soldier and to the community to which he returns would be for him to find himself not wanted and not regarded as a valuable asset to the community. To give him money or even to provide him with a stopgap job will fall far short of these requirements. In order for him to become a useful civilian citizen it is very necessary that his own individual value to the community should obviously to him remain high. This will require very careful planning and very generous and serious implementation.

Community responsibility is stressed in the literature on rehabilitation. There is much exhortation about it. Rennie¹ writes, "The whole purpose of psychiatric treatment may even be defeated by the unresponsive or negativistic attitude of the community or industrial employers." Rennie and Woodward⁹ are convinced that

The degree of social adjustment that men returning from the armed forces make and the speed with which they do it depend to a very real degree on the understanding they find among civilians, and on the way the people at home treat them. With understanding, reassurance, and constructive treatment, many of them achieve an acceptable status and carry on quite effectively after an adjustment period of a few weeks or at most a few months.

Farrell¹⁶ also believes that the tasks of rehabilitation are not singly those of the medical profession. He adds

Business also has a large measure of responsibility. They must be given every chance and encouraged to make good in industry. It is often remarkable how quickly even some of the most upset individuals return to their former life and efficiency in their productive work once the pressure that broke them can be removed.

The psychiatrist should take the lead, in the opinion of Finesinger and Lindemann,¹⁷ in organiz-

ing community resources. They write, "An educational program making available what we have to say to the general medical profession, to community authorities, social agencies, industrial personnel and clergymen should be the concern of our intensive thinking." They state that rehabilitation clinics are rapidly developing in different communities.

As suggested earlier in this review, one of the problems of rehabilitation is the disinclination of men needing help to seek it. Community efforts will have to be enticing to attract the veterans who are not desperate, or not unusually well educated in regard to mental hygiene, or not dependent enough to want and to accept what is offered. Millet¹⁸ is sanguine in this regard. He writes

Fortunately, large numbers will have highly constructive or hopeful attitudes toward their disabilities and be eager to take whatever specific retraining is necessary in order to be able to resume a life of self-support and independence. Such men may be counted upon to broaden the understanding of civilians as to the needs of other discharged men, and in some cases will provide excellent material for recruiting as experts in rehabilitation.

In spite of Braceland's¹⁰ charge, "It has been repeatedly stressed by industry as well as by the military services that a man must be fit for all duties or for none at all, and this all or none theory is the psychologic barrier which the returning veteran has to hurdle," it is to the credit of psychiatry and industry that for some years the larger industries, at least, have recognized the value of including psychiatrists or psychiatrically trained personnel directors on their staffs. Employment and employee-employer problems and the personality of the individual worker, as contrasted with the impersonal, exclusively monetary profit motive, had been given consideration and attention from the psychiatric or mental hygiene point of view long before the industrial rehabilitation difficulties of World War II arose.

The principal hazard in the present situation is that industrialists may be influenced by the popular articles of journalism to believe that it is well to be wary of the man who has been discharged for neuropsychiatric disability. How a division of the General Motors Corporation is meeting the issue of rehabilitation in industry is well delineated by Smith.¹⁹ He wrote in April, 1944, that the Delco-Remy Division had been keeping in touch constantly with about 5000 employees in military service. These men were sent letters, and gifts on various occasions, as at Christmas and Easter, and were told that they were wanted back when the war was over. Hundreds of letters had been received each week from the former employees. "Every letter that asks a question or indicates that a reply is desired is answered."

The policy of the Delco-Remy Division is as follows

Veterans will be given every possible assistance, sympathy, and consideration in helping them to get back into

the normal swing of civilian life. However, it is not our intention to oversympathize, coddle or lead them by the hand. In our opinion such treatment will simply lead to untold trouble in the future, as it develops in the individual the feeling that he is different from other people, entitled to special considerations, and that the world owes him a living.

This policy includes the decision not to give veterans preferential treatment. Although the plan of setting them apart from the general group of employees was considered, it was decided "that the veteran should, to all outward appearances, be treated as all other incoming employees." Smith states that a great majority of over one hundred veterans questioned on this plan preferred to be considered as no different from their fellows. This is the particular desire of that group of veterans who have been discharged from military service because of some slight mental or physical impairment which made them unfit for life in the service.

At the time Smith's report was written the Delco-Remy Division had employed 475 veterans. It was found that these men fell into two general classes. The first comprised battle-incurred disability discharges and men discharged as unfit for service because of some slight mental or physical disability. The rehabilitation of this class had not proved much of a problem and it was thought it would not in the future. The second class was made up of men who had been discharged because they were temperamentally unsuited for military service. Smith states, "This is the group who are emotionally unstable, and in the vast majority of these cases these characteristics were not acquired in the service but are inherent."

Smith's analysis of this type of veteran and the troubles he initiates is perspicacious. This man was a problem before the war, and now that he is a veteran he is more of a problem than ever, taking advantage of being classified as a veteran. He decidedly wants preferential regard. He can do no heavy lifting because of back injury.

He has calcified glands in his chest and objects to working in any dusty environment, he has an alleged heart condition and must do extremely light work, or he has defective feet and must sit down. He is the "misfit," and generally you will find that he was a "misfit" in society before he entered the service.

The author sees him as a potential danger to the industrial rehabilitation program. Since the man draws and necessitates attention and supervision, there is the danger that he may become a false symbol of the whole body of veterans. Smith believes that industry does owe these men a fair chance. "We will go even further with them than we would with the ordinary employee." He rightly enough thinks, however, that their rehabilitation is not basically industry's but that of society as a whole. He cautions that it is in relation to this type of veteran that pressure groups may arise. A union may charge that big business is being unfair

to an ex-soldier when actually industry is doing all that it can to help an incompetent. Smith concludes

The number of veterans who return with physical or mental impairment will be relatively small in relation to the total in service. This job resolves itself to simply handling each case on an individual basis, taking into consideration capabilities as well as limitations, assisting him to choose the work which he will be able to do best in order that he may be a self-sustaining member of society for the balance of his productive life, doing all this without emotionalism or paternalism — helping him to help himself.

If industry throughout the country could carry out the purported policy of the Delco-Remy Division, it would seem that the veterans' reinstatement would be wisely directed.

To help industry, especially the small and moderate-sized companies, which employ the major portion of American labor, in the work of readjusting service men and women to industrial jobs, the Subcommittee on Psychiatry of the National Association of Manufacturers Medical Advisory Committee has prepared a pamphlet, *Readjustment to Civilian Jobs*. The pamphlet is for distribution to management and contains an explanation of what neuropsychiatric disability means, suggestions for placement interviews and a plan for classification and placement in accordance with the psychiatric and personality impression given by each applicant.

The pamphlet is designed for use not only with the ex-service man but also with the demobilized war worker. It reads in part

It is possible that the greater problems will come from the ranks of these war workers. These war industry "employment neurotics" were the product, primarily, of emotional difficulties arising from their failure to adjust to employment requirements and, in many instances, although to a lesser degree, to their failure to adjust to abnormal living conditions in war industrial centers, and to new and unusual social relationships. In attempting to solve their emotional problems, the war-industry neurotics shifted their jobs in large numbers.

The plans for placement consist of estimating the applicant's personality, abilities and disabilities, carried out by a consulting psychiatrist or personnel director, or, if neither of these is available, by the company doctor or the applicant's own doctor, in conjunction with members of the managerial staff, also temporary job placement, providing for "a period of mutual 'on-the-job observation' between the applicant and the employer," when there is doubt about the worker's stability or capabilities.

Comparatively simple as all this may seem, if industry generally could be made aware of the possible value of psychiatric screening and direction, postwar employment difficulties would at least be ameliorated.

There is much literature for public guidance on how the returning service man and woman should be treated. One of the shorter of these, *When He Comes Back and If He Comes Back Nervous*,²⁰ is suitable for families who may want suggestions or

advice Besides explaining briefly how and why war experience may change the man who has been in service, it contains a number of sound "do's" and "don't's" Also, Pratt's² book, referred to previously, contains a large amount of generally useful information

CASE 31291

PRESENTATION OF CASE

A sixty-one-year-old man was admitted to the hospital because of fever, chills, malaise and weight loss

The patient had been well and active until about four months before admission, at which time he began to feel weak and tired He had sudden chills and fever and remained in bed for several weeks He took small doses of quinine without consulting a physician Three months before admission he developed severe spontaneous nosebleeds, for which he was admitted to a community hospital, where he remained for three months While at the other hospital he ran a septic course, with a chill and a sharp temperature rise to about 103°F almost every afternoon It was necessary to pack the nose because of repeated spontaneous hemorrhage The red-cell count fell from 3,300,000 on admission to 2,400,000 at the time of discharge The white-cell count varied from 7000 to 15,000, with as many as 93 per cent neutrophils A platelet count was 65,000, the bleeding time 2¼ minutes, the clotting time 3¾ minutes, and the prothrombin time 20½ seconds A tourniquet test was negative The

*On leave of absence.

urine was normal The serum nonprotein nitrogen was 30 mg per 100 cc The Hinton and Wassermann tests were negative X-ray and physical examinations of the heart and lungs were negative One blood culture showed diphtheroids Several blood cultures showed *Staphylococcus albus*, and two cultures yielded colon bacilli Examinations for malarial parasites were repeatedly negative Tests for agglutinins against typhoid, paratyphoid and dysentery bacilli were negative He was given sulfadiazine until it was learned that the *Staph albus* grown from the blood was resistant to sulfonamides He was given up to 20,000 units of penicillin every hour for several weeks During penicillin therapy the blood cultures became negative, but he continued to have chills and a fever of 103°F The teeth, sinuses, nose and throat and the genitourinary system were thoroughly studied by consultants and were said to be negative An intravenous pyelogram was normal X-ray films of the bones were normal Penicillin was stopped, and the blood culture promptly became positive for *Staph albus* Sulfadiazine was given in high dosage, and a blood level of 15.2 mg per 100 cc was obtained After two weeks the sulfadiazine was stopped because of hematuria, crystallinuria and a nonprotein nitrogen of 72 mg per 100 cc Fluids were forced and the patient became edematous, whereupon the fluids were limited The urine soon became negative Considerable abdominal discomfort, of which he had begun to complain, was relieved by enemas The blood cultures remained negative after the administration of the second course of sulfadiazine until three days before he was discharged, at which time *Staph albus* was again obtained Shortly before discharge the serum albumin was 2.15 gm, and the globulin 3.75 gm per 100 cc, an albumin-globulin ratio of 0.57 This test was repeated, and the albumin was 1.84 gm, and the globulin 4.16 gm At the same time the serum nonprotein nitrogen

was normal, and the sedimentation rate 14 mm per minute. X-ray films showed marked gaseous distention of the intestines, with a high diaphragm, especially on the right. The temperature varied from 100 to 106°F. Many moist rales were heard in the chest posteriorly. He was transferred to this hospital in an ambulance.

Physical examination revealed a thin, pale, drowsy man who appeared chronically ill. There was moderate pitting edema over the sacrum and of the lower extremities. Respiratory excursions were shallow. The diaphragm was high on both sides. There was dullness at both bases posteriorly, considerably more marked on the left than on the right. Breath sounds and vocal and tactile fremitus were markedly diminished at the left base. Moist crepitant rales were present at both bases. The heart was slightly enlarged to the left. The rate and rhythm were normal. No murmurs were heard, and the aortic second sound was equal to the pulmonary. The abdomen was markedly distended but not tender, there was shifting dullness, but no fluid wave could be elicited. The liver and spleen could not be felt.

The temperature was 99.0°F, the pulse 90, and the respirations 23. The blood pressure was 165 systolic, 105 diastolic.

Examination of the blood showed a red-cell count of 2,400,000, with 7 gm. of hemoglobin, and a white-cell count of 9800. The differential showed 78 per cent neutrophils, 17 per cent lymphocytes, 3 per cent monocytes and 2 per cent eosinophils. The stool was brown, formed and guaiac negative. Serum and spinal-fluid Hinton tests were negative. The urine was cloudy, had a specific gravity of 1.014 and gave a + test for albumin, the sediment contained 3 or 4 red cells, 12 to 20 white cells, with occasional clumps, a rare granular cast and many bacteria per high-power field. An abdominal paracentesis yielded 2800 cc. of light-yellow, slightly hazy fluid. The specific gravity was 1.008, and the sediment contained 115 white cells (mononuclears) and 45 red cells per cubic millimeter. A culture showed no growth. The serum nonprotein nitrogen, chloride and carbon dioxide levels were normal. The protein was 5.13 gm. per 100 cc., with an albumin-globulin ratio of 0.9. The cephalin flocculation test was ++++ in twenty-four hours. The prothrombin time was 24 seconds (normal, 18 to 20 seconds). A bromsulfalein test showed 60 per cent retention forty-five minutes after 5 mg. of dye per kilogram of body weight had been injected. A blood culture yielded no growth. The urine grew abundant colonies of colon bacilli. An x-ray film of the chest showed the right half of the diaphragm to be high in position, but both sides moved well. The liver was thought to be considerably enlarged. There were areas of increased density in the right middle and lower lobes. The heart was prominent in the region of the left ventricle. A gastro-intestinal series was negative.

The patient felt weak and frequently became flushed. The paracentesis relieved him completely of a moderate amount of dyspnea. He ate poorly, frequently refusing a meal. He was given four transfusions and frequent intravenous injections (dextrose, Amigen and physiologic saline solution). During the first week he showed a low-grade fever, the temperature rising to 101°F every evening. During the second and third weeks the fever was more erratic, with daily spikes sometimes reaching above 103°F. The pulse and respirations spiked with the temperature.

On the third day the liver was palpable two finger-breadths below the costal margin. On the fourth day the patient complained of a stiff neck. A lumbar puncture revealed normal spinal fluid, except for a gold-sol curve of 5554333100. Peritoneoscopy showed a normal-appearing liver that did not seem to be enlarged, the peritoneum was smooth. A liver biopsy showed no abnormality.

On the tenth day he again became markedly dyspneic. On the following morning he complained of sharp pain in the right chest anteriorly. The right dome of the diaphragm was found high and considerably more elevated than the left. Breath sounds in the right lung field were markedly diminished, and a moderate number of fine moist rales were heard. Examination of the legs was negative except for edema. An abdominal paracentesis yielded only 100 cc. of fluid. An x-ray examination of the chest showed considerable change since the observations made shortly after admission. The right lower lung field was diffusely hazy, and there was evidence of fluid within the pleural cavity. It was impossible to determine the position of the right leaf of the diaphragm. At the same time the urine contained innumerable white cells, many in clumps, and bacteria. The white-cell count was 36,500, with 9 gm. of hemoglobin. The stool was for the first time guaiac positive. There was no pain or tenderness in the abdomen or back.

On the sixteenth day the patient became incontinent and spoke in a disoriented fashion. Weakness and weight loss progressed. After several transfusions the serum protein was 6.1 gm. per 100 cc. The nonprotein nitrogen, chloride and van den Bergh remained normal. The white-cell count on the twentieth day was 21,000, with 94 per cent neutrophils. He became severely dyspneic again and slightly cyanotic and was relieved somewhat by an abdominal tap, which yielded 1800 cc. of thin yellow fluid. No fluid was obtained by thoracentesis.

On the twenty-second day the chest began to fill with fine rales and wheezes. Severe dyspnea returned. The pulse was 120. He was digitalized rapidly with Cedilanid. When pulmonary edema became alarming, he was given oxygen and tourniquets were applied to the extremities. The following morning he went into peripheral collapse and expired.

DIFFERENTIAL DIAGNOSIS

DR WYMAN RICHARDSON As usual I have two possibilities in mind Was this primarily infection or primarily tumor, possibly with secondary infection? This time I am going to rule out tumor as a primary cause of the disease because the only one I can think of as a possibility is lymphoma, and the whole course of the disease seems to be more that of infection The thing that bothers me a little is the rapidly increasing anemia in the beginning, which is perhaps more than one would expect with ordinary infection, although it is possible

This case brings up the question of how much to believe the evidence from a hospital with which we are not familiar. I do not wish to be "stuffy" about that, but when one is around a hospital, one realizes the difficulties of the laboratory and has opinions about the methods employed and whether or not the laboratory procedures can be considered important or reliable There is some discrepancy between the laboratory findings at the other hospital, and one finding in particular, the positive blood culture for *Staph albus*, deserves attention *Staph albus* showed up with great regularity when the patient was in that hospital In this hospital, apparently the physicians in charge were not too interested in the blood cultures because only one is noted, at least in this protocol, and that was negative So I am left a little in doubt whether to take the finding of *Staph albus* seriously It is a frequent contaminant On the other hand if it appears in two flasks regularly, following a rigid technique, one has to believe it. The question is, When does one begin to believe it?

The other thing that I want to comment on in regard to the original laboratory work is the platelet count of 65,000, with a normal bleeding time and tourniquet test I teach the students in the course in laboratory diagnosis that the platelet count is not worth doing I believe that is true The reports of technicians who have spent a lifetime doing these counts are of some value, but as they are usually done they cannot be depended on One can look at blood smears, if the platelets are diminished, allowance being made for the number of red cells, one can arrive at some definite conclusion When the platelets are normal in number they clump and cannot be counted I do not believe that the platelet count of 65,000 is important

This whole story sounds primarily like infection to me We might try to tackle this problem from the organs chiefly involved, that is, the kidneys, liver and lungs The x-ray studies of the lungs at the first hospital were negative, but later there was something that suggested difficulty involving the chest. Involvement of the kidneys appeared right after the patient had been on sulfadiazine for a considerable period of time, and involvement of the liver came on after that period, so that one begins to think of the possibility of some sort of infection, perhaps complicated by the use of large

amounts of sulfonamides That is about as far as I can go with the case I have come to a conclusion in regard to what this infection might have been, but I think that I should like to look at the chest plate now I might say that what I am thinking of is whether this man had thrombophlebitis with septic infarcts, whether he had phlebothrombosis with noninfected infarcts, whether he had multiple abscesses in the lungs, whether he had pulmonary tuberculosis or some such process or whether he had atelectasis from a high diaphragm

DR GEORGE W HOLMES I think that we can rule out a few of the possibilities I do not believe there is any evidence of miliary tuberculosis or anything resembling it I do not believe that he had miliary abscesses in the lungs, or abscess of any kind There is a high diaphragm on the right side, if one can believe the report that it moved freely, it was probably due either to a large liver or to some degree of atelectasis There is a line running out just above the diaphragm that could be the end result of localized atelectasis, but it is not definite The heart, I think, is perhaps within normal limits Because of the high diaphragm on both sides the heart lies horizontal in the chest and therefore seems larger than it is The curve of the left ventricle is a little prominent, and he may have had some enlargement of the left side of the heart The aorta shows tortuosity, but no more than what a man of his age should have. There is no calcification in the walls, and no evidence of mediastinal tumor

The films taken about a week later show increased density on the right side of the chest and what looks like fluid in the pleural space, perhaps with consolidation in the lung fields One wonders if this could have been a terminal affair The left lung still shows no essential change The heart has rotated a little so that it may be slightly displaced, but I doubt it Evidently this film is an attempt to see whether or not he had esophageal varices There is no evidence that he had them There is nothing in the examination of the stomach, it was said to be negative, and what films we have confirm that

DR RICHARDSON I am still in a quandary Incidentally, we have no history of injury to account for a portal of entry for this organism, which is important Dr Castleman tells me that the patient was a Greek, born in Greece What was his occupation?

DR BENJAMIN CASTLEMAN He was in the tonic business

DR RICHARDSON Perhaps he took too much of his own tonic Some Mediterranean people have a tendency to liver disease I do not believe that we have to consider echinococcal disease in this case

So it comes down, as far as I am concerned, to a blood-stream infection without any obvious portal of entry to account for the illness before he arrived in this hospital, and I am inclined to take the blood culture of *Staph albus* seriously in that it appeared

to be somewhat affected by therapy I think that the history suggests that he had pulmonary infarcts. We know that a partial collapse of the right lung base, with fluid, is not an infrequent finding in the presence of abdominal fluid and liver disease, and that may be the whole explanation. We know that he had a urinary-tract infection and have to say that he had a pyelonephritis. The question is whether that is the only lesion or whether there are others.

I am still trying to decide whether he had thrombophlebitis from the onset. I think that I shall accept *Staph albus* septicemia as the diagnosis in the first hospital, as a result of the septicemia, he may have had abscesses elsewhere, including renal abscesses. I believe that he was given sulfonamides in proper doses, but he had had them for such a length of time that toxic effects may have occurred, therefore I shall have to bring up the question of a toxic effect on the kidneys.

Finally, one has to explain the liver. There is no evidence of liver infection that I can see. There seems to be evidence of diffuse involvement of the liver. I might parenthetically state the evidence for that: a 60 per cent retention with a large dose of bromsulfalein, a ++++ cephalin flocculation test, a reversal of the albumin-globulin ratio, with a quite marked increase in the globulin at the other hospital (the total protein had gone down when he reached this hospital, but he still had increased globulin here), slight increase in the prothrombin time (probably of no significance), and ascitic fluid that was a transudate rather than an exudate. It is possible to suggest that this man had a toxic involvement of liver as a result of the sulfonamides. It is, however, a rather rare condition, and I assume that this man had some underlying liver disease to start with.

I shall say specifically that this man had a bloodstream infection, possibly due to *Staph albus*, pyelonephritis, possibly multiple abscesses, pulmonary infarction and toxic hepatitis superimposed on cirrhosis.

DR J H MEANS We struggled with this diagnosis in much the same way that Dr Richardson has. The patient was desperately ill when he entered, although he was not running a fever. Later he ran a septic fever. In my first note, I said "I cannot make a diagnosis. He has, I believe, some undrained pus somewhere. At least it must be searched for. There is considerable evidence of liver involvement. He could have a liver abscess." Then we thought of lymphoma, and I stated farther along that the studies were indicated, especially of the liver. Just as Dr Richardson thought, because of the 60 per cent dye retention, the ++++ cephalin flocculation test, the low albumin-globulin ratio and so forth, I made this note, "If it is cirrhosis, the hair-on-the-chest rule will have been broken because he has plenty of it." A liver biopsy was said to be negative. Still later I wrote that the

patient had been running a fever since the punch biopsy, had a leukocytosis and had developed right pleural effusion, and I wondered if there was any relation between the procedure and the subsequent events. We never established that there was. I begged the surgeons to search for pus somewhere, but I could not sell the idea to them. That is as far as we got.

The final diagnoses were liver disease and urinary tract infection, we thought that the signs in the lungs were due to pulmonary edema. We investigated the urinary tract, colon and gall bladder in the hope of making a diagnosis, but that is as far as we got. We thought that he had liver abscess in all probability. He did not have meningeal signs, and a lumbar puncture was negative. Dr Benedict saw no peritoneal lesions when he did the peritoneoscopy, and he could not establish anything in the lymphoma category.

This will turn out to be an interesting case. I know that it brings up the point that one will not make the correct diagnosis unless one thinks of all the possibilities. The past history was talked about a little, but insufficiently. We obtained no history of what would have given the clue to what the pathologist found. If we had gone at it harder and perhaps more expertly, we might have got it, but the patient was said to have been well until the sequence of events that led to his death began.

DR FRANCIS D MOORE At the time that I saw this patient the problem was whether he had right subdiaphragmatic abscess, either secondary to some focus that was back of the whole disease picture or secondary to peritoneoscopy, following which he developed more fever. It was difficult to settle the matter one way or the other. He did not have much tenderness in a region of the right eleventh and twelfth ribs and there was none in the upper quadrant. As a matter of fact, in relation to the final proved diagnosis, the absence of abdominal signs in either hospital, other than the signs of fluid, was interesting. At the time that I saw him I was not sure that he did not have subdiaphragmatic abscess. He was much too sick to explore.

DR MEANS I was not being critical. We thought it was good judgment on your part. I am trying to throw out the thought that we did bring up the possibility that he had pus that could have been drained and asked the surgeons about it. We could have been criticized had we not done so. At entry he had some suggestion of ileus, but it did not amount to much.

DR RICHARD H SWEET Was there any history suggesting antecedent appendicitis?

DR MEANS None that we could obtain.

CLINICAL DIAGNOSES

Pyelonephritis
Liver disease (? abscess)
Pulmonary edema

DR RICHARDSON'S DIAGNOSES

Septicemia (? *Staph albus*)
 Pylonephritis
 Multiple abscesses?
 Pulmonary infarction?
 Toxic hepatitis, with underlying cirrhosis?

ANATOMICAL DIAGNOSES

Periappendiceal abscess, chronic
 Peritonitis, acute fibrinous, pelvic
 Thrombophlebitis of superior mesenteric, splenic
 and portal veins (pylephlebitis)
 Liver abscesses, multiple
 Pancreatic abscesses, multiple
 Abscess, lesser omental sac
 Ascites
 Bronchopneumonia

PATHOLOGICAL DISCUSSION

DR. CASTLEMAN The autopsy on this man showed a lot of fibrin and pus in the pelvis that was well on its way to organization. The upper abdominal cavity contained about a liter of clear fluid. The liver was slightly enlarged, and between the head of the pancreas and the right lobe of the liver was a large abscess that extended into the pancreas. Smaller abscesses were scattered throughout the entire pancreas. When the liver was sectioned we found two or three large abscesses, but the most striking finding was in the venous system. The main portal vein and all its radicles were filled with pus and purulent thrombi. These thrombi had extended into the splenic and superior mesenteric veins. We looked then, of course, for the appendix, since it is well known that pylephlebitis is most frequently caused by acute appendicitis. The appendix was extremely small and covered with fibrous tissue and rather porky, fatty tissue. There was no evidence of acute inflammation, but we thought that it might well have been the source of the pylephlebitis a month previously. Microscopically the appendix showed a chronic process. It is conceivable that the abscesses in the pancreas might have had something to do with the production of the pylephlebitis, but I rather think they were secondary to the abscesses in the liver. There was a pyelitis and a mild pyelonephritis. The lesions in the lungs proved to be bronchopneumonia.

DR. RICHARDSON What was the organism?

DR. CASTLEMAN We cultured the abscesses of the liver and found nonhemolytic streptococci and *Staph albus*, and from the blood we obtained nonhemolytic streptococci and colon bacilli. I think that perhaps the staphylococcus was not a red herring.

DR. MOORE This boils down to the question whether acute appendicitis can give pylephlebitis without rupture or without being gangrenous.

DR. CASTLEMAN The appendix might have ruptured. It was extremely small, and we could not find a definite tip. It is possible that the tip had completely organized over a period of several months. The fact that the infection that we did find in the abdominal cavity was located in the pelvis points more to the appendix than to any other organ. There were several loops of small bowel adherent to the exudate in the pelvis, but there was no abnormality in the intestinal tract.

DR. MEANS I should like to ask the surgeons whether anything could have been done if the diagnosis of suppurative pylephlebitis had been made when he first came in.

DR. SWEET Nothing, unless one is dealing with a large single abscess, which is not the case in pylephlebitis.

CASE 31292

PRESENTATION OF CASE

A twenty-day-old male infant was admitted to the hospital because of vomiting and diarrhea.

The infant was born at term, weighing 7 pounds, 2 ounces. The delivery lasted one hour. The mother said that the baby had vomited before it was discharged from the maternity hospital but there were no other feeding difficulties. At home the formula consisted of 12 ounces of whole milk, 10 ounces of water and 3 tablespoons of Karo. Vitamins A, C and D were given in adequate amounts. The baby fed well but vomited each feeding a few minutes after it had been taken. The parents were not certain that the vomiting was projectile. Proper belching did not prevent vomiting. The infant had six to seven bowel movements a day, which were green and liquid. The mother stated that the baby had had a rash on the buttocks when he left the hospital and that she thought that he had had diarrhea while in the hospital. Two days after the baby arrived at home, his formula was changed to skimmed milk and water, with no improvement. A few days later Dextrin-Maltose was added, to be omitted again after a few days. The baby had lost 1 pound, 2 ounces, before admission.

Physical examination revealed a dehydrated infant who was ashen gray. The anterior fontanelle was sunken. The child measured 20½ inches and weighed 6 pounds. There was a marked rash on the buttocks. The ears, nose and throat were normal. The lungs were clear to percussion and auscultation. The abdomen was soft, and the umbilicus showed a slight serous discharge. Peristalsis was normal. No masses were felt. The extremities were normal.

The temperature was 99.0°F, the pulse 130 and strong, and the respirations 34.

Examination of the blood showed a red-cell count of 4,500,000 and a white-cell count of 18,700. The stools were liquid and green and contained no blood. The urine was normal. The blood was Type O,

Rh+ The serum nonprotein nitrogen was 22 mg per 100 cc, and the protein 3.4 gm

The child was given nothing by mouth, being fed parenterally. He was started on sulfadiazine as soon as hydration was established, and from the next day on he was also given penicillin. He continued to have small green stools. A lumbar puncture was negative, and culture of the cerebrospinal fluid showed no growth. After forty-eight hours on parenteral-fluid therapy, he was given skimmed milk and Karo by mouth. Within ten hours the number of stools increased to such an extent that these feedings were promptly discontinued. No pathogenic organisms were grown from the stool. A culture of the discharge from the umbilicus grew colon bacilli. A blood culture on admission was contaminated, and one on the fifth day showed no growth. Cultures from the nose and throat showed chiefly *Staphylococcus aureus*. The sulfadiazine level, based on two determinations, was about 5.0 mg per 100 cc.

The child seemed greatly improved on the fourth day. Physical examination showed that he was well hydrated. The nose, throat, ears, lungs and urinary tract were negative for signs of infection. The rash on the buttocks had cleared, and there were three small dark green stools that day. The temperature had continued to be normal since admission.

The next morning the child suddenly became cyanotic and went into circulatory collapse. The extremities were cold. The respirations were 22 but were labored, with some sternal retraction. The heart sounds were of poor quality. The abdomen was distended, and the liver was not enlarged. Peristalsis was normal. The stools, which had been guaiac negative, became positive. X-ray examination of the chest and abdomen was negative. The child was given plasma, 10 per cent dextrose in water and physiologic saline solution intravenously and was placed in an oxygen tent. The white-cell count on the fifth day was 3250, with 75 per cent neutrophils, the hemoglobin was normal. Three hours before death, bilateral swelling was noted over the mastoid region. The eardrums appeared normal. The temperature, pulse and respirations continued to be normal. The child expired quietly on the evening of the fifth day.

DIFFERENTIAL DIAGNOSIS

DR DARIO MORELLI Before we attempt to arrive at the cause of vomiting and diarrhea in this infant, I should like to comment on one point which to me is exceedingly important and which has been omitted, that is, the details of the birth. A great deal of information can be derived from points concerning the type of birth, the condition of the baby at birth and the immediate postnatal as well as the neonatal period. We are told that the infant was born at term and weighed 7 pounds, 2 ounces, and that the delivery lasted one hour. This is quite a

long time for delivery, unless it is meant to indicate the whole period of labor. Obviously they must have had some difficulty in the delivery of this child, if delivery is interpreted as the second stage. It was probably a dystocic one, and the possibility of some injury in the process of being delivered has to be kept in mind. We do not know, however, what the condition of the baby was immediately following birth, and so far as the neonatal period is concerned, we have only some vague statements from his mother. She thought that the child might have vomited and that he might have had diarrhea while in the hospital.

At home the vomiting increased to such an extent that he was vomiting after each feeding and the diarrhea was rather marked. The various causes of vomiting in an infant vary from trivial conditions to some which represent serious disease. I am sure that we can rule out most of them very easily.

Air swallowing is one of the very frequent causes of vomiting and that mechanism is quite clear. If the baby swallows air during the taking of food, the air bubble is quite readily expelled and may bring with it food previously ingested. Also, too frequent feedings or too large a volume of food given at one time may cause vomiting. Undue manipulation, improper handling of the baby and unsuitable composition of food have been mentioned as causes of vomiting. Then we have vomiting due to obstruction, such as pyloric stenosis, or obstruction in the intestine, such as intussusception or atresias in the duodenum or in other portions of the intestine. Allergy, pyloric spasm and intracranial lesions are also responsible for vomiting in children. In evaluating the causes of vomiting in this child, his feeding seems to have been adequate and the formula well constituted. We do not know the interval between feedings but we assume that they were offered every three or four hours. The child was apparently "bubbled up" carefully. We can rule out air swallowing even if he did swallow air, the mother took care in getting it out of the stomach. We can rule out pyloric stenosis; there was no visible gastric peristalsis, the vomiting was not known to be projectile, and there was no constipation. Intestinal obstruction seems unlikely in that he was having a great number of stools, furthermore, the course of the child's illness certainly does not suggest it.

So we are left with two possibilities, an intracranial condition and a parenteral infection. Parenteral infections are often the cause of vomiting in childhood, especially at the onset of the condition. Before we go any farther with the vomiting let us consider the causes of one of the other symptoms that this child presented, that is, the diarrhea. Unsuitable composition of the food is one. There are a great variety of specific enteric infections, such as bacillary dysentery, typhoid fever and paratyphoid fever, and there is also the extremely im-

portant group of parenteral infections that cause diarrhea in the newborn or in the small child. It immediately emerges from these few considerations of the possible cause of vomiting and diarrhea that we have one condition common to both — parenteral infection. As a matter of fact he was so treated after he first came to the hospital. Very wisely they hydrated him before starting sulfadiazine. The sulfadiazine was followed by penicillin. There is no question that the attending physicians were thinking in terms of infection, and they instituted a careful search for the location of the infection. Apparently the upper respiratory tract was normal. The urine was negative. The ears, throat and nose were said to be normal, although some reservation can be made at this point. I do not doubt the sincerity of the observation but it is known that examination of the throat and ears in a dehydrated infant is certainly a difficult task, not so far as accessibility is concerned but because the appearance of these structures may be quite changed by the dehydration and the throat may not appear infected when it is. We know that often even the most experienced observers have difficulty in deciding whether or not the throat is inflamed in any given case. The same can be said in reference to the ear. Apparently this baby was treated for infection, and the likeliest one was parenteral. The stools did not grow any pathogenic organisms.

Another interesting point is that he had a discharge from the umbilicus. A moderate discharge from the umbilicus is often seen and may be totally insignificant. Certainly a minimal amount of infection is present in a great number of infants and does not constitute any threat to the child's health. It is only when there is infection that spreads to the neighboring tissues causing cellulitis, when this has happened, if the umbilical veins are not fully thrombosed, as in the first two or three days of life, infection may spread through them and cause a general sepsis and involvement of the peritoneum. However, the growth of colon bacilli in a culture from that discharge is probably not significant, but it may indicate something more important than what we are willing to ascribe to it. It is unfortunate that the blood culture on admission was contaminated. It would have been of tremendous importance in deciding whether or not he had sepsis. It was repeated on the fifth day, but by that time the child had received quite a bit of penicillin and one wonders if a positive culture had been affected by the treatment.

The rash on the buttocks is to my mind not specific. It is not described and is only classified as marked. It may have been due to the enormous number of stools that the child was having. It may have been the expression of a simple "diaper dermatitis." The rest of the skin was apparently normal. The rash, however, cleared up after the baby had been in the hospital for four days. One

wonders if better care had contributed to that improvement. I think the crux of the whole case is deciding whether this baby had an infection and, if he had, whether it was a parenteral infection or an infection somewhere else, also, whether he had a birth injury, and finally, what caused the baby's death.

I have little doubt that this baby had infection, with vomiting and diarrhea, and it gives me courage to note that in the hospital they apparently thought the same way and treated him for infection. The possibility of birth injury is suggested to me by the fact that delivery lasted one hour. If it was a breech delivery one could speculate on the possibility of intracranial injury, as well as injury to the adrenal glands. At least it is an interesting point to consider. We finally come to the fact that the child had apparently been almost cured. On the fourth day the baby was greatly improved; he was well hydrated, and he did not show anything wrong on physical examination. The stools were few, although the abstract does not say whether they were loose or were formed, possibly they were formed. The next morning he suddenly had a dramatic episode of cyanosis and respiratory collapse. I have been thinking strongly in reading this history of the possibility that I just mentioned — injury to the adrenal glands. We know that the adrenal glands at birth are extremely vascular and highly friable. They are easily damaged and respond to infection in a dramatic way. They may become the site of massive hemorrhages, which manifest themselves with a picture of circulatory collapse, cyanosis, difficult breathing and distention of the abdomen. Hyperthermia and cutaneous hemorrhages may or may not be present. Certainly one should entertain that possibility, and I cannot erase it from my mind, even though I may be wrong in the last analysis.

There is another point of interest in that three hours before death bilateral swelling was noted in the mastoid region. At birth, pneumatization of the temporal bone has barely begun, there exists only one cell, — the mastoid antrum, — and the mastoid process is undeveloped. Development takes place some time later. The antrum is frequently the site of infection, especially following middle-ear infection, which in turn we can say is one of the most frequent findings in infants with acute nutritional disturbances. It sounds to me that this bilateral swelling might well have indicated subperiosteal abscesses in the regions of the antrums. That possibly ties up with the fact that we believe that the child had infection, which caused the vomiting and diarrhea, and that he possibly had a birth injury, and I daresay that possibly his death was due to massive adrenal hemorrhage.

DR ALLAN M BUTLER. I certainly agree with Dr Morelli regarding parenteral infection in a youngster like this. We have a clue to infection in the um-

bilicus, namely, the culturing of colon bacilli at three weeks of age. There are two questions concerning specific bits of information that I should like to ask. What did the urine show in terms of white cells and culture? What was the contaminant in the blood culture?

DR BENJAMIN CASTLEMAN The urine was not cultured. It was clear on admission, and the sediment contained 2 or 3 white cells and 2 or 3 epithelial cells per high-power field. The second specimen contained no cells. The blood culture contaminant was *Staph albus*, in one flask only.

DR BUTLER I was wondering if it was a colon bacillus, thinking of colon-bacillus septicemia, where so frequently there are hepatitis, pyelonephritis or infection elsewhere in youngsters of this age.

One might add that the bulging over the mastoid antrums previous to death brings up the whole question of the significance of such infections in many patients of this age group with nutritional disturbances. Way back in 1684 and again in 1920 a great deal of significance was attached to the organisms found at autopsy in such patients. This case received a lot of chemotherapy. It would, therefore, be interesting to know what the cultures from the middle ear and mastoid antrums showed. Such pus has been found to contain almost every variety of organism.

In obtaining the history it would have been important to check with the nursery from which this baby came to see if there was an epidermic diarrhea of the newborn or some such diarrhea as that described by Buddingh and Dodd.¹

DR CASTLEMAN The record states that the mother shared a room with someone else's baby who had the same symptoms.

DR GERTRUD REYERSBACH The hospital was called and denied that there had been any diarrhea.

CLINICAL DIAGNOSIS

Diarrhea
Bronchopneumonia?
Umbilical infection

DR MORELLI'S DIAGNOSES

Sepsis
Suppurative otitis media, involving both mastoid antrums
Hemorrhage into adrenal glands
Birth injury?

ANATOMICAL DIAGNOSES

Suppurative otitis media and mastoiditis, bilateral

Hemorrhage into adrenal glands, bilateral
Acute enteritis

PATHOLOGICAL DISCUSSION

DR CASTLEMAN At autopsy this baby's middle ears were filled with pus, which had extended into the mastoid antrums on both sides. We cultured the material on one side and recovered colon bacilli. I can find no note about what was recovered from the other side. We cultured colon bacilli from the pleural cavity. In the small and large intestines there were numerous ulcers, those in the large bowel being as large as 6 mm in length. They were fairly superficial, however, not extending deep into the mucosal layers. Cultures from these ulcers showed only colon bacilli. I do not believe that there is any question that the baby died of sepsis.

As Dr Morelli suggested, the adrenal glands were involved. The entire medulla of one was filled with blood. It had not enlarged the gland particularly, and was not a really big hematoma, but it probably was sufficient to account for the attack of collapse. The other adrenal gland had merely a few small hemorrhages, this was undoubtedly the same process to a lesser degree. I suppose it fits into the Waterhouse-Friderichsen syndrome, which can occur with any type of infection, not necessarily one caused by the meningococcus. The brain in this case was normal.

DR BUTLER Of course this youngster did not respond to intravenous glucose and saline as so many youngsters do who have adrenal difficulty underlying the clinical picture of collapse and dehydration.

As already indicated this case brings up the whole argument of the importance of considering antrotomy in patients with nutritional disturbances and some evidence of middle-ear infection. The argument often given by otolaryngologists is that one does not need to do an antrotomy because the communication between the antrum and middle ear is excellent. On the other hand, Marriott² used to say that the communication frequently was not free and that there was an accumulation of pus in the antrum that could not be relieved by opening the middle ear. Did you find as much pus in the middle ear as in the antrum? Was there any evidence of communication between the two?

DR CASTLEMAN We found pus in both antrums and middle ears, with good communications between them.

CONGRATULATIONS TO THE HERALD

In an editorial in the June 24 issue of the *Boston Herald* attention was called to the danger of sensitization to the sulfonamides, even in small doses, when introduced into the body in various ways. It was further emphasized that dressings, ointments, powders and so forth containing such agents can still be bought without a prescription, except in New York City, where the Health Department has banned the indiscriminate sale of these products as well. The *Herald* conservatively states that the free sale of any sulfonamide "complicates practical therapeutics." The promiscuous use of such drugs has certainly created numerous and disabling complications, and the *Herald* is to be congratulated

for the emphasis to its readers of the risks of such medication.

This is an excellent example of the way in which the press can disseminate valuable medical information to the public. Possibly this comment was stimulated by a committee of the Massachusetts Medical Society. It is to be hoped so, for to gain the full support of the press in the release of medical facts and figures of value to the citizens of the community is one of the best means of educating the public regarding matters of this sort.

SEVERE PNEUMONITIS CAUSED BY A NEW PSITTACOSIS-LIKE VIRUS

A GREAT deal has been written in recent years about the so-called "virus pneumonias," but little is actually known concerning the etiology of the vast majority of these cases. Few if any of the several viruses that have recently been described have as yet proved to be of etiologic significance in more than an occasional case or a small group of cases. Thus, the virus of ornithosis has been recovered from only a few patients with pneumonia, and the development of antibodies against this agent has been demonstrated in only a few others. In most, if not all, such cases there was a history of reasonably definite exposure to infected birds. The condition is quite analogous in this respect to human infections with the closely related psittacosis virus. The rickettsia of Q fever has rarely been identified as the cause of pneumonia, the notable exception being an outbreak that occurred among the workers at the National Institute of Health.¹ In that outbreak the mode of infection was not definitely established, since those who were afflicted had not been directly exposed to the agent. The rickettsias were being cultured in the laboratory, however, and the pathogenicity of the agent and its mode of spread are such as to make an occurrence of this sort quite possible. None of these agents have proved to be the cause of the large number of cases of primary atypical pneumonias that have been encountered in both the military and civilian populations of this country. Furthermore, the etiologic significance of all the other agents that have been described has not been confirmed.

A recent outbreak of severe pneumonitis in Louisiana²⁻⁵ is of interest because of the finding of a new virus transmissible to animals and apparently spread by contact with infected patients. The epidemic occurred in six isolated communities in the bayou region of Louisiana, the cases being scattered over an area of approximately 20,000 square miles. The disease was recognized as an entity only after an epidemiologic study of 3 cases had been undertaken. It was unusual in that it spread only among nursing contacts and had a high mortality, there being 8 deaths among the 19 recognized cases.

The first case was that of the wife of a trapper, who developed a febrile illness on December 2, 1942, she became progressively worse and was transferred to a sanatorium about 120 miles from her home, where she died on December 18. A nurse who attended this patient and her husband, who likewise helped care for her, both became ill on December 24. The nurse was treated at the sanatorium, where she died on January 6. Before that time, however, she was the source of 6 other cases in nurses and in persons who acted as nurses. The husband became ill after returning home and died on December 26. Of the secondary cases, only the fatal ones spread the disease, and the same was true of subsequent cases. Rigorous control measures were instituted, and after that time, except for an attendant who developed the disease while she was still in quarantine, no further spread occurred. It is of interest that the fatal cases were contagious only during the last forty-eight hours of their disease.

The incubation period was estimated as being between six and nineteen days. Transmission was only through direct contact with cases; no evidence could be found of living or intermediate vector, nor were human carriers or mild cases discovered. There were many possibilities of animal reservoirs, but few of these were adequately explored.

In the course of the epidemiologic studies it was discovered that a similar epidemic had occurred in March, 1936. The clinical picture, as described by the physician who attended the cases, was quite similar. In addition, secondary cases occurred only in the nursing contacts of the fatal cases and there were 5 deaths among the 7 secondary cases that were traced.

The clinical features were characteristic in all cases. The onset was mild, with headache and backache followed by slight chills, sweating and a concurrent abrupt rise in temperature. Pneumonitis was demonstrated early by physical and x-ray examinations. In spite of that fact the patients presented the appearance of well-being throughout the first week and into the second week of their illness and then abruptly went into a state of collapse. This was often accompanied by delirium and cyanosis, and the syndrome sometimes recurred at intervals until recovery or death. The white-cell count was low or normal, only occasionally being slightly elevated. Death usually occurred between the seventh and fifteenth days, and in one case on the thirty-ninth day. The febrile course in those who recovered lasted from two to five weeks. Convalescence in all cases was prolonged, several months usually being required before normal health was restored. Transient alopecia occurred in 3 patients.

Autopsies in 2 fatal cases showed similar changes in each. The lungs revealed sharply defined areas of plum-colored consolidation, an alveolar exudate chiefly composed of large mononuclear cells, hyperplasia of the alveolar lining cells and slight or no involvement of the bronchioles or bronchi. No significant bacteria were found, but a few clusters of minute, basophilic, coccobacillary, cytoplasmic inclusions were seen in the pulmonary alveoli, as well as in the Kupffer cells in one of the cases. The anatomical findings resembled those of psittacosis but showed little in common with those of Q fever.

A virus was obtained from throat washings in 3 of the 4 cases that were tested, and in 2 fatal cases it was also isolated from autopsy material. It was propagated in white mice by either intraperitoneal or intranasal inoculation and in guinea pigs by intraperitoneal inoculation, using either the throat washings or tissue suspensions. The symptoms and gross lesions in animals were similar to those observed with the psittacosis group of viruses, and there were readily demonstrable elementary bodies in stained smears of the spleen, liver and lungs of the infected animals. Guinea pigs respond with a fatal infection, and mice succumb when they are inoculated by any of the usually used routes, that is, intranasally, intraperitoneally, intracerebrally, intramuscularly

or subcutaneously No other known virus exhibits a similar pathogenicity, and for this reason the virus is probably new

The possible origin of this new virus in the wild life of the bayou region, its apparent relation to other psittacosis-like viruses, the severity of the disease and the viral spread by contact from fatal cases signify that the virus is an important infective agent. Furthermore, the pathogenicity of the virus for laboratory animals appears to be such as to make it easily recognizable should it be looked for in the future

MASSACHUSETTS MEDICAL SOCIETY

POSTWAR PLANNING COMMITTEE

The value of co-operation between physicians, hospital executives and hospital trustees was emphasized at a meeting called by the Postwar Planning Committee on June 20 Representatives of the ninety-eight hospitals in Massachusetts having a capacity of 100 beds or more, including the trustees, the superintendents and the chiefs of the medical and surgical services, met at the invitation of the committee to discuss various aspects of the problems involved in providing adequate opportunities for the postgraduate training of doctors returning from the service at the end of the war, for the extension of postgraduate instruction to all doctors in Massachusetts and for the promotion of health education among the laity Stimulating suggestions were made by various speakers, one suggesting that a trustee of a large metropolitan hospital, by serving also as a trustee in a hospital at a distance, might bring about an exchange of ideas that would be of benefit to both institutions It was pointed out that an increase in the number of residencies would also improve the care given to hospital patients

Among the guests of the committee were nine members of the Massachusetts General Court, who, by their presence, evidenced the increasing interest of legislative representatives in the progressive activities of the Society

It is to be hoped that this meeting will be followed during the next two or three months by similar meetings in various communities of the Commonwealth

HOWARD F ROOT, *Chairman*

DEATH

HAMMOND — William J Hammond, M D, of East Walpole, died July 4 He was in his seventy-seventh year Dr Hammond received his degree from Harvard Medical School in 1899 He was a member of the American Psychiatric Association, the New England Society of Psychiatry, and the Association for Research in Nervous and Mental Diseases and a fellow of the American Medical Association His widow survives

NEW HAMPSHIRE MEDICAL SOCIETY

DEATH

HILDRETH — Lewis G Hildreth, M D, of Marlboro, died June 25 He was in his seventy-eighth year Dr Hildreth received his degree from the Kentucky School of Medicine in 1892 His widow, a daughter and four sons survive

MISCELLANY

ALVARENGA PRIZE TO DR WIENER

In recognition of his important work on the various Rh blood factors and on their genetic transmission, the College of Physicians of Philadelphia, on July 14, awarded the Alvarenga Prize to Alexander S Wiener Dr Wiener will give the Alvarenga Lecture before the College of Physicians of Philadelphia and the Philadelphia County Medical Society on October 3, the title being "Rh Blood Factors in Clinical Medicine"

The Alvarenga Prize was established by the will of Pedro Francisco da Costa Alvarenga, of Lisbon, Portugal, an associate fellow of the College of Physicians, "to be awarded annually by the College of Physicians on each anniversary of the death of the testator, July 14, 1883" The College usually makes this award for outstanding published work, inviting the recipient to deliver the Alvarenga Lecture

CORRESPONDENCE

MAX MEYERHOF

To the Editor Word has come from Mizraim An old doctor died in Cairo, and funeral services were held for him in the Ashkenazi Synagogue on April 23 He was an eye specialist, who also wrote several books on the scientific heritage of the Arabs, according to the obituary column in the *New York Times* For further identification of the dead, it was mentioned by the newspaper that he was the cousin of a physiologist who had won the Nobel Prize in 1922 Ten short lines, fifty words in all, at the tail end of a narrow column, to summarize the achievements of a long life of scientific research!

Max Meyerhof originated from a family of distinguished scientists and physicians His maternal uncle was practicing gynecology in Breslau when he was born in Hildesheim on March 21, 1874 Perhaps the memory of his uncle moved him to take up medicine as a profession He studied at Hannover, Heidelberg, Berlin and Strassburg, where he graduated in 1897 Bacteriology was then a novelty, and young Dr Meyerhof spent a year (1898) as assistant bacteriologist in the Public Health Institute of Strassburg, studying the biology of the diphtheria bacillus and the mysteries of *Proteus vulgaris*

This year also brought him closer to his young relative Wilhelm Spiegelberg, professor of Egyptology at Strassburg University The lectures of his cousin awoke in him a long-

ing for the land of ancient culture and hieroglyphs. This longing was stimulated further by his postgraduate studies in ophthalmology (1899), at the Berlin and Breslau eye clinics he learned that Egypt is rich not only in hieroglyphs but also in eye diseases. After a preliminary trip to the land of pyramids in 1900, he decided to emigrate from Germany.

In 1903 Meyerhof arrived at Cairo and began his ophthalmologic practice. The next year he was already a member of the Ophthalmological Society of Egypt. Since Cairo is a city of many nations and many languages, where a successful medical practice requires a real linguist, Meyerhof devoted several years to learning Hebrew, Arabic, Persian, Syriac, Turkish and other Oriental languages. These studies brought him closer not only to his patients but also to his colleagues and to the scholars of his adopted land. And the metamorphosis began—Meyerhof, the ophthalmologist, developed into Meyerhof, the medical historian.

During the period of his first stay in Egypt (1903-1914) he was chiefly the eye specialist, the medical practitioner, whose observations and essays filled many pages in the bulletins of his society. He found a veritable museum of eye diseases in his office: purulent conjunctivitis, corneal granulations of all types, eyes affected by leprosy, vernal conjunctivitis, tumors of the eyelids, all types of foreign bodies. He investigated all stages of trachoma, the causes of the disease and its immunological peculiarities, and his interest in this subject remained alive even in his later years.

For his ophthalmologic research he was honored by his Egyptian colleagues, who, in 1909, elected him, the thirty-five-year-old foreigner, to the presidency of the Ophthalmological Society. In this office he showed himself a real benefactor of Egypt by organizing a nation-wide service for the treatment of eye diseases and by establishing an ophthalmologic department at the King's Hospital in 1910.

His frequent visits to the libraries of Cairo, and the stimulating contact with such friends as the scholarly Ahmad Taimur Pasha, led him toward a new field of activity—medical history in general, and the history of ophthalmology in particular. His first medicohistorical study appeared in the 1906-1907 volume of an ophthalmologic journal, and was soon followed by others. He fell in love with Clio, and with the ancient Arabic manuscripts in the Library of the Khedive and in the private collections of Egyptian noblemen. Then, World War I ended his happiness for a period.

His forced volunteering as a physician in the German army resulted in a waste of ten years (1914-1923). After the war, he had to stay in Hannover, where, engaged in medical practice, he waited for a change in the political atmosphere of Europe. In 1923 he was allowed to return to Egypt, only to find part of his library dissipated and some of his notes lost. But he started all over again, this time as Meyerhof, the Arabic scholar and historian. A series of journal articles and books, all of them based on painstaking investigations, is the result of this second period of his productive life.

In 1926 he found the Syriac and Arabic translations of certain treatises of Galen, treatises lost for us, both in the original Greek and in the Latin version. He also showed us the importance of Arab culture in every branch of modern science in the book *Le monde islamique* (Paris, 1926). Two years later, on its centennial celebration, the Egyptian University published his main work, a critical edition of *Ten Treatises on the Eye* (Kitab al-ashr maqalat fi'l-ain), ascribed to Hunain ibn-Ishaq (809-877). By editing the Arabic text with a translation of this rare manuscript, Meyerhof's contribution to science was invaluable, since Hunain's work is not only the earliest existing textbook on the eye and its diseases, but also the starting point of Arabic ophthalmology. For it he justly received an honorary Ph.D. degree from the University of Bonn and an honorary membership in the Royal Society of Medicine in London.

There are many more manuscripts in the old libraries, and from 1928 to 1938 we became acquainted with the work of many other early Arab and Persian physicians, through the researches of Meyerhof in the *Paradise of Wisdom of Ali at-Tabari* (Iss, 1921), the ophthalmologic *Al-murshid fi'l-kohl of ibn-Aslam al-Gafiqi* (Masnou, 1933), the abridged version of the *Book of Simples of ibn-Muhammad al-Gahqi* (Cairo, 1933-1940) and the pharmacologic work of Beruni (1933). His most widely appreciated finding (1933) is, however, the work of the thirteenth-century ibn-an-Nafis, whom he proved to be the real discoverer of the pulmonary circulation of blood.

The last few years of his life were again disturbed by another world war, and the persecution of his race. His interest turned to Jewish affairs, to the medieval Jewish physicians in the Near East and to that great Jew of the twelfth century, the second Moses, whose life ended in Cairo, Moses ben Maimon. His Maimonides studies are now left unfinished. Death also spoiled the great ambition of his life—to find the lost manuscript of the admirable work of ibn al-Haitham on the optics and vision.

In his adopted land he will be remembered as the German doctor who pitied the poor fellahs, with their bloodshot, discharging and blind eyes, as the great humanitarian who organized medical care for a plagued nation's relief. His many friends in the world will soon feel the loss of the foremost historian of medieval Arab medicine, who for many years kept the door of Eastern wisdom open for Western science. With his broad medical background, linguistic knowledge, and love of old moldy manuscripts, he represents to me the ideal medical historian, whose empty home in Cairo now turns into the lost Kaaba of many a planned pilgrimage.

USE OF THE WORD "ANTIBIOTIC"

To the Editor: It has now been about three years since the terms "antibiotic" and "antibiotic effect" were suggested by Waksman, Horning, and Spencer. The fact that these expressions have gained wide acceptance in a short time shows that they have answered a real need for such terms. There are, however, good reasons for questioning the propriety of limiting the application of so broad and useful a word as "antibiotics" to one particular category of substances that are destructive to life. Certainly many products of the manufacturing chemist, such as the arsenicals, the mercurials, and many different types of radiant energy are true antibiotics. The agents that are now being obtained from various forms of bacteria and lower fungi might be referred to simply as bacterial or fungous antibiotics, or from a semantic standpoint the word "mycoantibiotics" has much to commend it. In any event, I venture to suggest that the field of usefulness of the word "antibiotics" should not be circumscribed by conventionally limiting its application to one group of substances alone, especially when from an etymologic viewpoint such restricted use of the term hardly seems justified. Should the word come to be used in a more general sense than being confined to the "mycoantibiotics," then other similar expressions, such as "chemoantibiotics" and "actinoantibiotics," would probably come into use as special group terms.

BOOK REVIEW

Gynecological and Obstetrical Urology. By Houston S. Everett, M.D. 8th, cloth, 517 pp., with 220 illustrations. Baltimore: Williams and Wilkins Company, 1944. \$6.00.

The twenty-three chapters that make up this book offer its readers a review of urology. Anatomy, physiology, diagnosis and treatment are discussed from the experiences of the Gynecological Department of the Johns Hopkins Hospital and University.

It is questionable whether a book of this size can adequately cover the entire field of urology, even when limited to the female patient. Gynecology and urology meet in many conditions, such as urinary fistulas, tumors of the urethra, inflammatory changes and cancer. This common ground is important to both specialists and deserves more consideration than this book provides, since so much space is devoted to urology alone. Much more could have been written on the management of urinary-tract complications that follow operation and on irradiation of the female genital tract.

The author is an enthusiastic follower of the teachings of Hunner, many of whose principles have not been accepted by the average urologist. Those who believe with Hunner, however, will read this book with great satisfaction.

THE SURGICAL TREATMENT OF CARCINOMA OF THE RECTUM*

Statistics on 198 Cases of Resection

E. PARKER HAYDEN, M.D.†

BOSTON

CARCINOMA of the rectum and sigmoid is often encountered and is much more frequent in that segment than in other parts of the colon. It seems unnecessary to discuss the symptoms of this disease or to advance any arguments in favor of surgical treatment as against radiotherapy. It is doubtless generally agreed that radical surgery should be carried out whenever possible. In the presence of one or two metastases in the liver, or when the local growth, although extensive and perhaps abscessed, can still be removed, I have always completed the operation if possible, being willing to accept a higher mortality rate for the sake of giving relief, if not cure, in this unfavorable group of cases. Thus it is that of 217 patients explored, in only 19 was the carcinoma found to be so extensive as to make a radical procedure foolhardy, whereas in 198 the growth was removed by one of the several types of radical operation (Table 1). The evolution of operative procedures, from the limited posterior excisions of the 1880's and 1890's

None of these methods permit so thorough a removal of mesentery as does abdominoperineal resection, yet surgeons do use all of them and obtain cures. Their relative frequency in my experience is shown in Table 2. The safety of a single-stage

TABLE 2 *Methods of Resection*

TYPE OF OPERATION	No. of Cases
Abdominoperineal resection	
One stage	131
Two-stage	27

Mikulicz resection	10
End to-end suture	13
Tube resection	1
Total	198

abdominoperineal resection, with adequate pre-operative preparation, is such that I now rarely resort to a two-stage procedure, other than an occasional cecostomy as a preliminary decompression for marked obstruction.

The two-stage procedures, used in 27 cases, consisted of three methods: colostomy followed by posterior resection, the Jones operation, in which the colon is not divided at the first stage but is brought out as a loop colostomy after dissection of the pelvis, and the Lahey procedure, in which the sigmoid loop and mesentery are divided and separated at the first operation, both bowel ends being brought out through the abdominal wall. Dr. D. F. Jones often emphasized the risks involved, after dividing a sigmoid, in placing the inverted and devitalized lower segment below the peritoneum and leaving it there a week or more before doing the perineal part of the operation. On two occasions, when I had planned a one-stage operation, the patient's condition at the end of the abdominal part of the procedure was such that I decided against perineal removal at that time, doing it two days later without any unusual sepsis or other complications. To have left the lower segment, with its reduced blood supply, in the hollow of the sacrum longer than forty-eight

to the present widely used abdominoperineal resection, has been based on a sound conception of what constitutes the most thorough removal of gland-bearing areas and primary lesions. Every surgeon is occasionally tempted to do something less than this, if the tumor is high enough in the sigmoid to permit either a resection with permanent colostomy and inversion of a short rectal stump, a Mikulicz resection or a resection with end-to-end suture

to the present widely used abdominoperineal resection, has been based on a sound conception of what constitutes the most thorough removal of gland-bearing areas and primary lesions. Every surgeon is occasionally tempted to do something less than this, if the tumor is high enough in the sigmoid to permit either a resection with permanent colostomy and inversion of a short rectal stump, a Mikulicz resection or a resection with end-to-end suture

*Presented at the annual meeting of the New England Surgical Society, Boston, September 20, 1944.

†Associate visiting surgeon, Massachusetts General Hospital.

hours would have invited infection, which might well have been serious or fatal. Only rarely should it be necessary to divide the operation in this way, but it can be done in an emergency.

Anterior resection may be used to avoid a perineal extraction if the tumor is too low for a safe anastomosis or a Mikulicz operation but high enough to permit division of the bowel below it with a fair margin and a satisfactory inversion of the rectal stump above the peritoneal level. To leave the stump below the peritoneum invites retroperitoneal infection, which may well be serious. This is an operation that I have not found to be satisfactory and that I rarely perform.

End-to-end suture can be done when a tumor is a little higher than just mentioned but not high enough for a Mikulicz operation, which requires a rather long lower segment below as well as above the tumor.

Tube resection, for a tumor too low for anterior resection, and when preservation of an anal outlet seems necessary, is an operation rarely indicated.

Abdominoperineal resection in one stage is the ideal procedure for carcinoma of the rectum and sigmoid, and offers the highest hope of a cure. I have rarely been compelled to abandon plans for this procedure because of a patient's refusal to have a colostomy. I have always thrashed out this question in advance with the patient, although not always saying flatfootedly that it would have to be done without question.

A stay of three to five days in the hospital before operation on the colon is usually an adequate period for general rest, preparation of the bowel, completion of laboratory work and whatever measures seem necessary to improve the patient as an operative risk.

Unless contraindicated I have used pontocaine spinal anesthesia, which greatly facilitates the ease of operation, as contrasted with the more difficult relaxation under ether. A moderate Trendelenburg position is sufficient, although a high one is better. The patient is sometimes bothered by too high an inversion.

I have usually placed the colostomy in the long left paramedian incision, without suture of the left lateral gutter, since there is about as much room for small bowel on the left as on the right side of the suspended colon. If the descending colon is brought out through a lateral rectus stab wound, the smaller lateral aperture should be closed, since there is much greater likelihood of small-bowel herniation with obstruction through a small aperture.

The perineal part of the operation I have carried out with the patient in the right Sims position. After removal of the bowel segment the posterior wound is packed with a large gauze handkerchief inside of a rubber dam, and the wound is sutured from its upper end down to the drain, which comes out anteriorly.

The colostomy is opened in twenty-four or forty-eight hours, an enema given on the fourth or fifth day, and boric irrigations of the posterior wound are begun after removal of the posterior pack at about the same time and continued until the discharge ceases.

The average postoperative hospital stay is three weeks.

In several cases I have removed the uterus and adnexa with the bowel segment, and occasionally part or all of the posterior vaginal wall. Resection of a loop of small bowel that has become involved in tumor by adherence to the main growth, with anastomosis of the ends, is sometimes necessary.

Of the resections in this series of 198 cases, 131 were performed over three years ago and 98 over five years ago, the remaining 60 have been done more recently and therefore have no end-result value. In every case where it was possible to do so, as previously stated, the growth was removed even if the outlook for cure was not good, and regardless of the age of the patient, if there seemed a reasonable likelihood of his surviving the operation.

In the entire series there were 26 hospital deaths, a mortality of 13 per cent, with autopsies in 11 cases. The chief causes of death are given in Table 3.

TABLE 3 Causes of Death in Hospital

CAUSE OF DEATH	No OF CASES
Pneumonia	8
Septis	7
Embolus	3
Obstruction	2
Shock	1
Anesthesia	1
Uremia	1
Coronary occlusion	1
Cardiac decompensation	1
Suicide	1
Total	26

These patients varied in age from twenty-seven to seventy-five, but 22 were over fifty-four.

The operations performed in these fatal cases are shown in Table 4. Although over 50 per cent of the deaths occurred in cases receiving one-stage resection, this should not be considered an indictment of the procedure, since actually the 14 deaths were only 10 per cent of the 131 single-stage resections—a mortality lower than that of the series as a whole.

TABLE 4 Operations Performed in Fatal Cases

TYPE OF OPERATION	No OF CASES

The deaths from embolism occurred in 3 cases in which operation was done in the present era.

of femoral-vein ligations It is of interest that thrombosis of one or both iliac arteries and their tributaries was found at autopsy in 2 of these, whereas in the third the pathologist could not determine the origin of the embolus

Of the 198 patients resected, 75 died later, in most cases of recurrent disease, 12 of these died of unrelated causes, and 96 are still alive Of the 98 patients operated on over five years ago, 32, or 33 per cent, have survived without evidence of disease for five to fourteen years (Table 5) The latest

TABLE 5 Radical Resections Performed Over Five Years Ago

Died in hospital	12	12
Died later	54	55
Alive and well	32	33
Total	98	

death from recurrent disease occurred five years and five months after operation

In general, the patients who died later of recurrence were the ones whose tumors were classified as Grade II or III adenocarcinoma, who had metastases in the lymph nodes at operation or who had a long history of symptoms and a large tumor invading the serosa and extending beyond it There were, however, exceptions to this Likewise, in the group of cured cases, were some with lymph-node involvement and a large tumor

SUMMARY

The surgical treatment of 198 cases of carcinoma of the rectum in which radical resection was performed is discussed A five-year cure rate of 33 per cent was obtained

A single-stage abdominoperineal resection is recommended, the operative mortality in such cases having been 10 per cent, compared with an over-all mortality of 13 per cent

DISCUSSION

DR FRANK H LAHEY, Boston I must say something about cancer of the rectum because of our large experience with it This is a fine series, and Dr Hayden is to be complimented It represents the standard of the country for carcinoma of the rectum as to operability, mortality and general results, and I do not believe that it could have been improved on materially Cancer of the rectum is still a field that can be improved, however, in terms of approach from the standpoint of the general practitioner and the public

Before I report our end results I should like everyone to recall a few things that we are not doing in cases of cancer of the rectum For one, we are not educating the general practitioners and the public enough to the fact that diagnosis does not have to be made solely by digital examination and does not have to be made by roentgenogram, but is to be found in the history in nearly all the cases Dr Swinton, in our clinic — I have repeated this statement a hundred times, but it contains such a lesson that I continue to do so, — studied 100 proved cases of carcinoma of the right colon, 100 proved cases affecting the left colon and 100 proved cases involving the rectum, and in reviewing the histories asked question, Was there blood in the stool, alter-

ation in bowel function or pain of an obstructive character? In these cases the answer was "yes" in nearly 98 per cent, in other words, the diagnosis could have been made almost by mail

We need to educate the lay public more along these lines About 3 out of every 100 persons have polyps of the large bowel and rectum We must approach cancer of the rectum and colon in the precancerous stage, and include in our procedures proctoscopic and sigmoidoscopic examinations and contrast enemas In many of these cases, a history can be obtained of blood in the stools long before carcinoma could have been present, indicating that the lesion was at first a polyp

I dislike to present our figures because they are always so large Nevertheless, I have to present them to you because it is from them that we must draw our conclusions

We have operated on 1800 patients for carcinoma of the colon and rectum, of whom 1200 or 1300 had carcinoma of the rectum and 500 or 600 had carcinoma of the colon It is interesting that the operative mortality was originally 103 per cent In the last five years for the whole group it has dropped to 50 per cent In the last two years the mortality in cases of carcinoma of the colon has dropped to 28 per cent, and that in cases of carcinoma of the rectum to 39 per cent

Our operability is much the same as Dr Hayden's, 85.5 per cent It is also interesting to realize that 9.6 per cent of the patients in whom we resected the rectum had metastases to the liver, and in about 22 per cent of the cases there was involvement of other structures, such as neighboring segments of bowel, the uterus, the bladder or some other structure In at least 60 cases we have removed the rectum, uterus, tubes, ovaries and part of the vagina If the whole series of patients is put together, including those in which other organs were involved and those with metastases to the liver, 53 per cent of them are alive and well after five years without evidence of recurrence It is important to remember that this series includes palliative operations, so that the over-all figure for the cases that were operable is higher

We have done two-stage resections of the type that I have described in about 400 cases We now do one-stage operations in about 81 per cent I agree with Dr Hayden that if one can see the pathological report, one can tell from this large experience about what will happen to these patients If there is no lymph-node or blood-vessel involvement and the lesion is limited to the section of bowel removed, 90 per cent of the patients will be alive and well for over five years without evidence of recurrence These are the favorable cases If there are lymph-node metastases, only 37 per cent will be alive and well without recurrence, and if there is involvement of other structures, such as neighboring sections of bowel, 30 per cent will be alive and well Unfortunately, if there is blood-vessel invasion the one thing that means recurrence only 14 per cent will survive for over five years

There is a school of thought in the country today, based on sentiment concerning the sphincter, that advocates limited procedures I have read and heard several papers on preservation of the sphincter and formation of perineal colostomies, and I believe that these are bad When one tries to accomplish two things one loses something in each — one cannot have one's cake and eat it, too, when one approaches the question of cancer I do not care how small the lesion is, if it is truly carcinoma, the resection should be all the more aggressive, because thus there is a better opportunity to cure these patients at that time When one tries to preserve the colon in terms of getting it down to the perineum, one unconsciously limits the radicalness of the procedure After all, who wants a colostomy in the perineum, where the only way one can see it is with a mirror? I should much rather have one where it can be taken care of, and it can now be well handled with all the plans we know for managing colostomies We sell no bags None of our patients wear bags They can be trained so to constipate themselves and substitute irrigation for defecation that they do not need bags Therefore I do not see any reason why we should do anything that can limit the radicalness of procedures for the removal of such tumors

In regard to colostomies, do not let these patients get away from your oversight for the first six months They lose their morale during that time and that is the time that they have to be educated regarding the colostomy There

must be someone to whom they can write or talk about their problems. Another thing is to teach them to establish what their bowel habits are to be, in terms of irrigation every two or three days. When these habits are established, they can do almost anything that they have done previous to the institution of the colostomy.

I think that colostomy has such a bad name because the palliative type, with a living death attached to it, is largely the only one about which people and physicians know. When more patients and physicians are familiar with the colostomy after the lesion is removed, they will realize that it is entirely different from the one in which the lesion is still present, causing most of the symptoms associated with palliative colostomy.

This is still a great field for advancement, and the paper of Dr. Hayden presents an admirable personal series, with fine end-results.

DR. DAVID CHEEVER, Boston. There are many here better qualified to discuss this subject than I, and I have little to say. I heard some of Dr. Hayden's paper and thought it excellent, and based on an extremely good record of personal results. I agree entirely with Dr. Hayden and Dr. Lahey about the necessity of educating the public about colostomy.

It is very interesting for the older men to think back over the general course of events in the history of the operation for carcinoma of the rectum—that is, to go back to the older days when, as I well remember, Dr. Maurice Richardson used to say, "If I had carcinoma of the rectum, I should go to the poorest surgeon I could find and ask him to do the most extensive operation he could do." The inference is obvious.

The greatest advance that has been made in one sense in the treatment of carcinoma of the rectum is the recognition, as Dr. Lahey says, that the perineum is the very worst place to have a postoperative opening, and that we are striving for an impossible ideal in making the anus where Nature placed it first. This was for years and years one of the greatest mistakes that we could have made, and it was only when we made up our minds that we should not strive for an impossible and impracticable ideal that we made further progress.

I also agree keenly with the idea that one way to educate people would be to let them see the favorable results in these cases, especially the comparative innocuousness of the artificial anus. I have always told my students that we ought to keep nearby in our great hospitals one of our many successful cases, in which an active person gets along very well indeed with an artificial anus and does not have to curtail his activities in the least. We ought to keep such a patient available to talk to prospective patients.

DR. LINCOLN DAVIS, Boston. Dr. Hayden's paper was extremely well presented and showed first-rate results, and it was impressive to me because it was such an improvement over the statistics of my time. I should like to ask Dr. Hayden or Dr. Lahey, since they both do radical resections in the presence of metastases in the liver, how long the patients live with metastases in the liver.

I have been told that there is a great difference in metastases of carcinoma in the liver between those from the stomach and those from the large intestine, that metastasis to the liver in cases of carcinoma of the stomach is practically a

bar to going on with the resection, whereas that in cases of carcinoma of the large intestine apparently is not. How long can one expect a patient to live with metastases in the liver?

DR. HAYDEN. I am afraid I cannot answer Dr. Davis's question, except by saying that I have knowledge of at least 2 patients who lived for four years with liver metastases. I have always removed the tumor if the liver was not extensively involved, and occasionally even under those circumstances.

It is perfectly obvious that Dr. Lahey's excellent results serve to emphasize what we all know, namely, that large numbers of cases, with increased technical experience, a good organization and first-class anesthesia, entirely aside from the excellent operative ability of the surgeons in the clinic, produce results that one would naturally expect and toward which we all ought to strive.

I am sure that several of my deaths should have been avoided. It is easy to figure this out afterward, but the important thing is to figure it out beforehand.

DR. LAHEY. I can answer Dr. Davis's question because I came prepared to do so. The patients with metastases in the liver who have been operated on, with radical removal of the primary tumor, have lived an average of twenty-five months after operation.

DR. HAYDEN. The patients with recurrences lived an average of two and a half years. Dr. Daland had some figures several years ago on the average duration of life in patients not operated on, which he may want to mention.

DR. ERNEST M. DALAND, Boston. Before this society nine years ago I presented a series of 100 cases of untreated cancer of the rectum, comparing it with a treated series. With absolutely no treatment the average duration of life was fourteen months. We also studied a series of 80 patients who had had colostomy only, and found that their length of life was no greater than that of the untreated group.

I should like to say a word in regard to our experience with cancer of the rectum at Pondville Hospital. At the present time we are operating with a greatly reduced number of beds. In 1941, when we were using 150 beds, we did 23 one-stage abdominoperineal resections, with a mortality of 11 per cent, and 5 colostomies and posterior excisions, with 1 death.

We believe strongly that one of the answers to low mortality is a long preoperative preparation. This can be done better in a state hospital than in some private hospitals. We ordinarily keep a patient for five to seven days and often two to three weeks before operation, getting him in condition so that he can go through an abdominoperineal resection.

I agree thoroughly with Dr. Lahey that the care of the colostomy is extremely important. We do not allow our patients to use bags when they leave the hospital, but quite a number have come back to the follow-up clinics with bags. We think that the patient with a colostomy needs no bag and should have no trouble.

In one of our follow-up clinics last spring I saw 13 patients who had had a radical resection for cancer of the rectum. I had some students with me, so I took pains to inquire about the habits of those patients in regard to their colostomies. Twelve of them said that they had absolutely no trouble. The thirteenth said that he had no control of it, possibly because he was an old man and drank too much beer.

THE FIRST YEAR OF THE EMERGENCY MATERNITY AND INFANT-CARE PROGRAM
IN MASSACHUSETTS

FLORENCE L. MCKAY, M D,* SALLIE SAUNDERS, M D,† AND ETTA BLOOM, A B ‡

BOSTON

THE Emergency Maternity and Infant-Care Program in Massachusetts completed its first year on September 2, 1944. The following discussion relates primarily to the administrative phase of the program rather than to the medical findings. Participating in this program were more than 2000 physicians and 130 hospitals, the latter representing nearly all the 137 licensed hospitals giving maternity service in Massachusetts. During the first year, 13,703 cases were authorized for care. Of these, 12,035 (88 per cent) were maternity cases and 1668 (12 per cent) were infant cases. The total expenditure of funds for the first year was \$591,644 76 ¢.

MATERNITY CASES

During the year in Massachusetts, there were approximately 85,000 deliveries, 14 per cent of which came under this program. Of these cases,

TABLE 1 Cost of Completed Maternity Cases

MONTH OF COMPLETION	NO OF CASES	EXPENDITURE	
		TOTAL	AVERAGE PER CASE
1943			
September to December 1944	71	\$5 683 41	\$80 05
January	105	8,542 12	81 35
February	207	18 441 60	89 09
March	410	38 126 93	92 99
April	507	47 936 28	94 55
May	582	55 475 12	95 32
June	744	71 252 49	95 77
July	1004	98 706 42	98 31
August	791	80 379 11	101 62
Totals	4421	\$424 543 48	
Average			\$96 03

4421 were completed during the year, with a payment of \$424,543 48 (Table 1). In 4276 cases, complete payments were made, in 145 cases, partial

The distribution of these cases in the different classifications of the armed forces were as follows: Army, 71 per cent, Navy, 22 per cent, Marine Corps, 3 per cent, and Coast Guard, 4 per cent. The average amount paid for each case was \$96 03. There was a steady increase in the cost per case throughout the year, from \$80 05 in 1943 to \$101 62 in August, 1944. The stay in the hospital averaged 10 6 days. The lowest amount paid on any one case was \$3 for one prenatal visit. The highest cost for a complicated case was \$380 85.

Of the total amount expended, 58 per cent went to hospitals, 40 per cent to physicians and 2 per cent to miscellaneous charges, such as clinic fees, nursing, ambulance, unusually expensive drugs, transfusions and anesthesia. The payments to private physicians were influenced by the fact that many cases were delivered without medical cost in Army or Navy hospitals or in the wards of the large city hospitals.

Table 2 shows the average amount spent on different types of care given to maternity cases.

TABLE 2 Average Expenditures for Various Types of Service

TYPE OF SERVICE	CASES RECEIVING SPECIFIED CARE		AVERAGE EXPENDITURE PER CASE
	NO	PERCENTAGE OF TOTAL	
Hospital	4259	96	\$58 23
Attending private physician	3608	82	45 58
Consultation	128	3	39 04
Nursing	68	2	7 61
Clinic	348	8	10 82

The average payment to the physician was less than the \$50 fee allowed for complete maternity care because of the fact that some patients moved from Massachusetts, so that they were under a physician's care in this state only a short time.

TABLE 3 Trimester of Pregnancy at Time of Application

TRIMESTER	MONTH OF COMPLETION				ALL CASES	
	NO	SEPT DEC Percentage	NO	JAN -APR Percentage	NO	Percentage
First	1	1	20	2	352	8
Second	1	1	250	20	1472	59
Third	69	98	959	78	2346	53
Totals	71		1229		4421	

payment was made because the patients moved, died or withdrew their applications.

*Director, Division of Child Hygiene, Massachusetts Department of Public Health.
†Assistant director, Division of Child Hygiene, Massachusetts Department of Public Health.
‡Principal statistical clerk, Division of Child Hygiene, Massachusetts Department of Public Health.
§The total expenditure through January 1945 was \$1 195 436 36.

Also, at the beginning many patients were admitted late in their pregnancy, and therefore did not receive complete maternity care under this program. This is more clearly brought out in Table 3, which shows the trimester of pregnancy at the time of application. Because this was the beginning of the program, the first completed cases were naturally in the

third trimester. The second year should give a better picture of the distribution of patients in the three trimesters applying for care.

The distribution of cost according to four-month periods for hospital and medical care (Table 4)

TABLE 4 *Average Payments to Hospital and Attending Private Physicians*

PERIOD	CASES RECEIVING HOSPITAL CARE			CASES HAVING AN ATTENDING PRIVATE PHYSICIAN		
	NO	PERCENTAGE	AVERAGE PAYMENT	NO	PERCENTAGE	AVERAGE PAYMENT
September-December	71	100	\$58.02	33	46	\$40.55
January-April	1194	97	56.89	968	79	43.77
May-August	2994	96	58.77	2607	84	46.32
Totals	4259			3608		
Averages		96	\$58.23		82	\$45.58

shows a fairly steady hospital payment throughout the year. The interesting feature is the increase in the percentage of cases having a private physician from 46 per cent in the first four-month period to 84 per cent, or nearly twice as much, in the last four-month period. The 46 per cent figure may be explained by the fact that the first cases completed were those that were cared for in hospitals where there was no charge for medical care. There was, however, a distinct increase in the number of patients having private medical care. This increase may have been influenced by the fact that after November 15, 1943, the hospital payments were made on the basis of ward cost per patient-day up to \$6. This made it possible, in some cases, for patients to be cared for in semiprivate rooms at ward cost, thus enabling physicians on the courtesy staff to deliver patients in the hospital. The table also shows that the payments to physicians increased gradually during the year, indicating that the later patients came under the program earlier in pregnancy and thus that more prenatal visits were paid for.

Of the 4421 maternity cases, 4357 (99 per cent) were carried through delivery, 25 women had precipitate deliveries in the home. In 4259 cases the program paid for hospitalization, the remainder used some form of hospital insurance.

The outcome of delivery is shown in Table 5.

TABLE 5 *Outcome of Delivery*

OUTCOME	NO	PERCENTAGE
Full term live birth	4026	92
Premature live birth	146	3
Stillbirth	97	2
Abortion	71	2
No report	50	1
Total	4390*	

*Greater than the number of deliveries because there were 33 cases of twins.

There were 4172 live births. Of these, 4026 (96.5 per cent) were full-term and 146 (3.5 per cent) were premature live births. The latter percentage is about that recorded in state well-child conferences and in the hospital reports of premature live

births. The 97 stillbirths represent a rate of 23.3 per 1000 live births, which agrees closely with the rate for Massachusetts in 1943 (23.5). There were 33 cases of twins, or 66 infants, of which 42 were full-term live births, 21 were premature live births

and 3 were stillbirths. Of the 4172 infants born alive, 52 were reported by the obstetric attendant as having died, 51 of them under one month of age. In all probability this does not represent the actual number of deaths. Many obstetricians turn over infants to pediatricians during the first two weeks, especially if they are ill. Thus, there may have been deaths among this group that were not reported by the obstetric attendant.

There were 7 maternal deaths during or after delivery. This represents a rate of 17 per 1000 live births, which compares favorably with the rate for Massachusetts for 1943 (2.0).

INFANT CASES

During the first year of the program, 315 infant cases were completed. An infant case was considered as completed when the infant had reached his first birthday.

The distribution among the divisions of the armed forces closely resembled that of the maternity cases—Army, 74 per cent, Navy, 22 per cent, Marine Corps, 2 per cent, and Coast Guard, 2 per cent.

During the first year infant care comprised payments for the sick infant, for health supervision at well-child conferences and, during August, 1944, only, for immunization (Table 6). In 83 per cent

TABLE 6 *Average Expenditures on Authorized Services for Completed Infant Cases*

TYPE OF CASE	CASES RECEIVING SPECIFIED CARE		EXPENDITURE	
	NO	PERCENTAGE	TOTAL	AVERAGE PER CASE
Total cases	315		\$13,791.73	\$43.78
Care of sick infant	263	83	13,692.23*	52.06
Hospital	111	35	9,806.48	88.35
Attending physician	207	66	3,114.00	15.04
Consultation	18	6	360.00	20.00
Nursing	9	3	93.63	10.40
Immunization	4	1	30.00	7.50
Health supervision at well-child conferences	49	16	69.50	1.42

*Includes \$318.12 spent for services other than the four designated ones.

of the cases payments were for the sick infant. The average cost for infant care was \$43.78, the lowest being 50 cents for health supervision, and the highest \$1480.63 for laryngeal stenosis.

Hospitalization in this group represented by far the greatest cost, even though only 35 per cent of all the infants were hospitalized. These infants had 2005 days of hospital care, an average of 18 1/2 days per case. Nineteen infants died, 8 being under one month of age. Immunization showed a small amount because this service became available only during the last month of the first year.

These 315 cases are too few to form the basis of an analysis from which comprehensive conclusions

may be drawn. They serve rather to indicate the trends to be expected in the increasing numbers that may be reported in the future.

SUMMARY

Certain administrative phases relating to the Emergency Maternity and Infant-Care Program in Massachusetts are discussed, with the aid of statistics derived from the first year of operation.

ACUTE ULCERATIVE COLITIS

-Report of a Case

FRED M. SULZBERGER, M.D.*

SOUTHBRIDGE, MASSACHUSETTS

ONE of the still unsolved problems in medicine is a condition described in the medical literature as "chronic ulcerative colitis." As yet no completely successful treatment has been evolved, and many confusing reports on the efficacy of various therapeutic measures are still to be found. Most authors agree concerning the symptomatology and consider that the disease is essentially chronic in nature, with acute exacerbations as a characteristic feature. The majority of writers also agree that a chronic ulcerative colitis may be caused by several different agents. In one form of the disease, for which no specific cause has as yet been found, the term "nonspecific ulcerative colitis" is employed.

The therapy of this form of ulcerative colitis is still a matter of personal experience and opinion. Reports of the results of dietary management, chemotherapy, serum therapy and different methods of surgical interference are reported with enthusiasm by some, but are discredited by others who have experienced no success with these methods.

A feature that is predominant in all the cases of nonspecific ulcerative colitis is the nervous personality of the patient, or some manifestation of an abnormal psychologic condition.

A survey of the literature on ulcerative colitis indicates that the term "chronic ulcerative colitis" is not satisfactory. There are some cases in which the disease runs an acute fulminating course that might properly be called "acute ulcerative colitis." This manifestation, which has been reported only occasionally, is of importance because of the tendency toward a rapid fatal outcome. Only in a few cases do therapeutic measures seem to be successful, and even in these a critical observer asks himself whether the recovery occurred independently of them or because of them.

The importance of an early diagnosis in acute fulminating cases is obvious, but this may be difficult at times, especially if the features of the disease are confusing and if sigmoidoscopy cannot be done. The following case history serves as an illustration.

CASE REPORT

E. F., a 29-year-old, married woman, was admitted to the Harrington Memorial Hospital on August 8, 1944. Four days previous to admission, she began to have diarrhea. She had eleven bowel movements on the 1st day, and the stool contained some blood and mucus and was very watery. There was no pain. The appetite was good, but the patient slept poorly. The day previous to admission she could take no food without vomiting.

The past history revealed little information. The patient had never been seriously ill. She had borne a child 8 years previously. Her married life was happy. Menstruation was regular. She had always been nervous, and the only time when she was mentally contented was when she worked in a factory and did not have time to think about herself. Six years previously she spent much of her time with a friend who had colitis and who talked incessantly about her disease. The patient became afraid that she would contract it, and possibly as a result had an attack of diarrhea. A diagnosis of colitis was made, but was never confirmed by an examination. During the last 5 years, she had several attacks of diarrhea, but did not move her bowels more than three or four times a day, and the attacks never lasted more than 3 days. These attacks were always connected with excitement or worry.

During the 7 months before admission the patient took care of her mother, who was suffering from cancer of the intestines and bladder. She thought that she might get cancer, and worried continually. She was also upset by her father, who was a chronic drinker and came home every night intoxicated. Once he tried to commit suicide by jumping out of the window, and she had to hold him back. From then on she stayed up every night until he was safely in bed. Her husband's joining the Navy added to her worries. Two weeks after the death of her mother, she left her home and went to visit her aunt. Ten days later her acute illness began.

Physical examination showed a thin, sick-looking woman, who was extremely nervous. The weight was 98 pounds (40 pounds underweight). The blood pressure was 110/80, the pulse 128 and the temperature 98.6°F. The tongue was coated. The lungs were normal. The heart was within normal borders, with the action regular but accelerated. There were no murmurs or abnormal accentuations. The abdomen was sensitive and somewhat tender throughout. The spleen and liver were not enlarged, and no tumor masses were palpable.

*Member of medical staff, Harrington Memorial Hospital, Southbridge.

Rectal examination revealed no abnormality. There was a slight exophthalmos, and a tremor of the hands and tongue. The reflexes were exaggerated. There was a slight papular skin rash.

The urine showed no albumin, sugar or bile, microscopical examination was negative. The hemoglobin was 87 per cent

watery. Since all the examinations, including x ray study showed no sign of colitis, it was thought that the patient had an intestinal infection, and she was treated accordingly. A sigmoidoscopy was proposed, but before the necessary arrangements could be made the patient insisted on going home, leaving the hospital against medical advice on the 5th day.

FIGURE 1

and the color index 1.05. The red-cell count was 4,160,000 and the white-cell count 19,500, with 77 per cent neutrophils, 19 per cent lymphocytes and 4 per cent mononuclears. Bacteriologic examinations of the stool and urine for paratyphoid and dysentery bacilli were negative. X-ray examination of the colon on the 3rd day showed no gross pathologic change (Fig. 1).

On the 2nd day, the temperature gradually began to rise (Fig. 2). The stools showed no blood or mucus but were very

Before she left, treatment with sulfaguanidine was started, and this was continued in her home by her physician.

The patient was readmitted on August 28. While at home, she had discontinued the sulfaguanidine treatment for some time and had then recommenced it in smaller doses. She had been running a temperature of 99°F in the morning and one of 101 to 102°F at night. She had had several watery bowel movements daily and had lost 7 pounds. Two days before admission she discovered a skin rash on both knees.

The physical findings were not much changed from those on the first admission, except that the patient appeared to be much sicker. The abdomen was slightly distended, and there were gurgling sounds in the intestines. There was slight pain on pressure on the right side of the abdomen. There was a skin rash on both knees, with round, oval pale-red swellings, slightly elevated and painful to touch. The pulse was 150 to 160 and of poor quality. The blood pressure was 110/90. The white-cell count remained at 15,000. Rectal examination again proved negative. The patient was apprehensive and anxious. She still had four to eight watery bowel movements every 24 hours, which never contained blood or mucus. She ran septic temperatures that reached 103°F at night and 99.4°F in the morning.

Three days after the second admission, the right knee joint became swollen and painful. The next day a slight systolic murmur was heard over the apex and mitral area. The spleen appeared to be enlarged and painful. The white-cell count remained between 15,000 and 20,000. The urine and stool were negative. An agglutination test for undulant fever and a blood culture were negative.

The clinical picture at this stage of the disease included a septic temperature (Fig 2), a rapid pulse of poor quality, a

sarv. This was performed on the following day. The cecum was thickened and red. Because of the patient's weakened condition, the surgeon did not explore farther. After the operation, intensive parenteral fluid therapy was administered, including plasma, blood and dextrose, but in spite of this her condition became worse daily. The temperature rose again, as did the white-cell count.

On the 10th day following operation, the patient developed a psychosis. She became extremely aggressive but was easily quieted. On the 11th day she became noisy, screamed if anyone came near her bed and insisted that the nurses and physician were going to poison her. On the same day the temperature rose to 103.4°F and the white-cell count to 30,000, and the patient died.

Autopsy (performed by Dr William Freeman). The entire colon had many ulcers, five of which had perforated the bowel at its rectal end. The serosa of these perforated areas was dark-red, soft and mushy and was surrounded by a thick bank of greenish-gray fibrinous exudate. There was practically no free fluid pus. In the remainder of the colon, beginning at the cecum, there were relatively few ulcers, which were shallow and involved only the mucosa. The edges of these ulcers were serrated but not hemorrhagic. Distally the

FIGURE 2

systolic murmur, an enlarged spleen, skin eruptions, an acute inflammatory swelling of one knee joint and a high white-cell count — the perfect clinical picture of a septicemia. There was still no objective proof of colitis. The negative blood culture proved nothing against the diagnosis of septicemia because of the previous medication with sulfaguanidine. An electrocardiogram merely showed a sinus tachycardia. An x-ray examination of the chest was negative.

On the 10th hospital day, 3 weeks after the first barium enema, another x-ray film was taken. This showed a tremendous change in the colon. Its outline presented a typical saw-tooth appearance along its entire course, characteristic of advanced ulcerative colitis (Fig 3). The last third of the large intestine seemed to be deprived of most of its mucosa. These x-ray findings established the diagnosis.

Up to this date every therapeutic measure had proved ineffective. When the diagnosis of probable septicemia was established, penicillin was given in doses up to 100,000 units every 24 hours for 5 days. Neither the patient's condition nor the temperature improved in any way, and on the 6th day this treatment was discontinued and sulfadiazine treatment was begun. This seemed to be more effective, inasmuch as the temperature slowly decreased and the white-cell count fell from 14,000 to 10,000. The enlargement and tenderness of the spleen, the swelling of the right knee joint and the skin rash disappeared.

After the x-ray examination had established the seriousness of the colitis, it was decided that an ileostomy was neces-

sary. This was performed on the following day. The cecum was thickened and red. Because of the patient's weakened condition, the surgeon did not explore farther. After the operation, intensive parenteral fluid therapy was administered, including plasma, blood and dextrose, but in spite of this her condition became worse daily. The temperature rose again, as did the white-cell count.

SUMMARY

A case of acute ulcerative colitis is presented, with several unusual clinical features indicative of the infectious process. These included a large tender spleen, swelling of the knee joint and erythema nodosum. Death occurred from the severity of the infectious process and multiple perforations of the bowel.

The lack of response to adequate penicillin therapy was striking, and suggests that this drug is of little

value in acute nonspecific ulcerative colitis. Similarly, an ileostomy was ineffective, presumably because of the fulminating nature of the condition.

Failure to make an early diagnosis was undoubtedly due to the fact that sigmoidoscopy could not be performed. The importance of this maneuver as a di-

FIGURE 3

The apparent response to sulfadiazine indicates that this form of chemotherapy should be fully attempted over an adequate period of time in cases of this severity.

agnostic measure in unexplained diarrhea is stressed. The importance of psychologic factors in aggravating the condition is demonstrated.

MEDICAL PROGRESS

BODY-FLUID PHYSIOLOGY THE RELATION OF TISSUE COMPOSITION TO PROBLEMS OF WATER AND ELECTROLYTE BALANCE*

DANIEL C DARROW, M D †

NEW HAVEN, CONNECTICUT

THE following paper summarizes recent work on the chemical structure of the body in as much as it is related to some of the problems of water and electrolyte balance. Some of the concepts are based on work that has not yet been confirmed, but enough is established to give a tentative outline of the changes in composition of intracellular as well as extracellular fluids.

CHEMICAL ANATOMY

From the point of view of balance of water and electrolyte, the chemical anatomy can be described in terms of three tissues. These are chosen because

water and electrolyte will not enter into the subsequent discussion.

The second category of tissues makes up the extracellular fluids and is typified by blood plasma. Table 1 gives representative examples of extracellular fluids. They all contain large amounts of sodium and chloride and relatively little potassium and magnesium. Although interstitial fluid contains much less protein than does blood plasma or lymph, it is not protein-free.³ The composition of the various gastrointestinal fluids and sweat is dependent on the activity of the glands. Cerebrospinal fluid contains more chloride than an ultra-

TABLE 1 *Approximate Composition of Various Extracellular Fluids*

of their size, and because their peculiar chemical composition characterizes other tissues, both as to composition and to the types of change that take place.

The first tissue is bone, which contains almost all the body calcium and extracellular phosphorus. The molecular ratio of calcium to phosphorus in bone is 1.057. This fact enables one to calculate the balance of cellular phosphorus from the balance of calcium and phosphorus. It is not usually recognized that calcified material contains about 1 mole of sodium for every 30 moles of calcium.¹ Thus, bone sodium is equivalent to about 10 per cent of the total body sodium in babies and about 33 per cent of that in adults.² Since this sodium is not available to the rest of the body fluids when combined in the calcified matrix, bone sodium can affect other body fluids only when extreme changes in calcification are taking place. Since significant fluctuation in the amount of bone calcium is not likely to occur in the short periods of time when a physician is concerned with problems of water and electrolyte balance, the effect of bones on tissue

filtrate of plasma, owing to some peculiarity of the so-called "blood brain barrier." All the extracellular fluids are derived from blood plasma, and a protein-free ultrafiltrate plasma may be used to represent the composition of extracellular fluids as a whole. Altogether, extracellular fluids make up 25 to 30 per cent of the body weight in babies and 20 per cent of that in adults. Total extracellular electrolyte is approximately equal to the volume of extracellular fluids times the concentration of the various electrolytes in an ultrafiltrate of blood plasma.

It is obvious that the preservation of the integrity of the extracellular fluids is intimately connected with the balance of sodium and chloride. The chief organ that regulates these fluids is the kidney. Indeed, the urine may be considered a highly modified filtrate of plasma that is elaborated and excreted for this purpose. It is obvious that extracellular fluids may increase or decrease in volume, as in edema and dehydration, they may show increase or decrease in electrolyte concentration, and there may be an increase or decrease in bicarbonate concentration, as in alkalosis or acidosis. Some mention of the effects of these various disturbances on total body electrolyte is given below.

*From the Department of Pediatrics, Yale University School of Medicine.

†Associate professor of pediatrics, Yale University School of Medicine, associate pediatrician, New Haven Hospital.

The third category of body fluids comprises the intracellular fluids. In addition to organic material and water, the cytoplasm is made up of relatively large amounts of potassium, magnesium and phosphorus and small amounts of sodium and chloride. Table 2 shows analyses of different tissues together with the probable proportions of extracellular and intracellular water and the probable concentrations of certain constituents per kilogram of intracellular water. The compositions of intracellular fluids are

this fashion, but heart muscle shows no demonstrable change in intracellular water in response to changes in concentration of extracellular sodium, and brain tissue tends to lose potassium⁶ and to keep intracellular water relatively constant. Intracellular sodium replaces deficits of skeletal and cardiac muscle potassium, but true deficits of liver potassium have not been demonstrated except in certain stages of shock.⁷ The errors involved, however, in considering that all intracellular fluids react like

†Expressed as amounts per 1000 gm of intracellular water

similar but not identical. The characteristic feature is a high concentration of phosphorus, potassium and magnesium and a low concentration of sodium and chloride. The amount of intracellular water is chiefly dependent on the balance of potassium but is indirectly influenced by the concentration of extracellular sodium.^{4,5}

From the point of view of the body as a whole, total intracellular fluids may be represented by the intracellular phase of skeletal muscle. This is permissible because 40 per cent of the body weight is made up of muscle, and this accounts for about

that of skeletal muscle are not large enough to invalidate this assumption as a means of visualizing a first approximation of changes in the composition of body water and electrolyte as a whole.

SCHEMATIC REPRESENTATION OF BODY WATER AND ELECTROLYTE

To represent the makeup of the body, Table 3 shows the approximate composition of a 10-kg infant.* Extracellular fluid is represented as 2.5 kg of fluid having the composition of an ultrafiltrate of plasma. Intracellular fluids are represented by

TABLE 3 The Extracellular and Intracellular Fluids in a Normal 10-Kg Child

*The composition of intracellular fluid is based on analyses of cat muscle.

†The table shows the usual concentrations and amounts of intracellular sodium and potassium. Actually, intracellular sodium may be practically zero and the concentration of intracellular potassium about 10 per cent lower in essentially normal rats and cats. Thus, the total intracellular sodium may vary from a trace to 54 mM and the potassium from 640 to 706 mM.

70 per cent of the total intracellular fluid. For a schematic presentation, the high proportion of muscle water is fortunate, since the changes in composition of muscle under various conditions can be described with considerable confidence.^{4,5} Thus, osmotic equilibrium between the intracellular and the extracellular phases of muscle is brought about by shifts of water into or out of the cells so as to bring about a change in electrolyte concentration about half as great as that in extracellular fluids.⁵ No shift of cations across the membranes seems to be involved. Liver tissue also reacts in

4.5 kg of fluid having the composition of the intracellular phase of the muscle. The data are based on analyses of cat muscle, but human muscle resembles cat muscle quite closely. Since it has been found⁸ that the composition of the muscle of rats shows certain variations without abnormalities in the serum, the limits of these variations are shown in a footnote to the table. It should be stated, however, that both rats and cats tend to have the higher

*An adult would be represented by the same proportions except that extracellular water would be less—20 per cent of body weight instead of 25 per cent. The tables represent only approximations, but since the important relations are quantitative, tables rather than diagrams are the best method of presentation.

levels of intracellular potassium and sodium, and this fact justifies the assumption that these values are frequent. When serum potassium is abnormally high, muscle potassium may reach even higher levels, usually with apparent loss of intracellular sodium.⁸ As is pointed out below, there is a tendency toward reciprocal relation between intracellular sodium and potassium in muscle. The low normal levels of muscle potassium, however, are not always accompanied by gains in intracellular sodium, and the high normal levels of muscle potassium do not necessarily lead to low intracellular sodium. Attention is directed to the considerable normal variation in body sodium and potassium that may arise from variations in so-called "normal" cellular composition of intracellular fluids.

The evidence for intracellular chloride is indirect⁵ and theoretical.⁹ Some evidence indicates that its concentration equals that of potassium in extracellular fluids. It constitutes a sufficiently small and constant fraction of total extracellular chloride so that it need not be considered in the present discussion.

Table 3, then, shows what may be considered the normal partitions in tissue composition when the normal variations of extracellular concentrations and volumes are not taken into consideration. Subsequent paragraphs will bring out the effects of normal as well as abnormal variations in the composition of intracellular fluids.

CHANGES IN BODY FLUID INVOLVING EXTRACELLULAR ELECTROLYTE

Previous discussions of the problems of body water and electrolyte have assumed that the cell membranes are practically impermeable to cations.¹⁰⁻¹² This surmise is known not to be true, for it has been demonstrated that both sodium and potassium readily cross cell membranes. Nevertheless, the distribution of these cations remains such that many phenomena can be described by assuming that adjustments to changes in the sodium concentration in extracellular fluids will be largely brought about by shifts in water. Thus, with a decrease in concentration of serum sodium, water enters the cells so as to reduce the concentration of intracellular potassium in muscle and liver and probably many other tissues.⁵ If there is increase in concentration of serum sodium, water leaves the cells so as to increase the concentration of intracellular potassium. The process is the same as the swelling and shrinking, respectively, of erythrocytes in hypotonic and hypertonic salt solutions. Hence, the volume of extracellular fluids depends chiefly on the total amount of extracellular sodium and extracellular water can be maintained at the expense of a drop in serum sodium concentration. Diminution of extracellular volume frequently accompanies abnormal concentrations of extracellular electrolyte and probably accounts for the fact that such con-

ditions are grouped together under the term "dehydration." Total body water, however, may be normal when serum concentrations are low because the cells contain too much water. Also, total electrolyte is usually diminished in amount when serum concentrations are high, because high concentrations usually mean that there is not enough water available for the kidney to carry out its function of adjusting electrolyte concentration. Generally, some sodium and chloride have been excreted before the shortage of water has led to the rise in concentration. The important point is to realize that the central feature of clinical dehydration is practically always a deficit of extracellular electrolyte, and that this may or may not involve gross deficit in total body water.

The mechanisms of the various symptoms of dehydration are not clear. Space is not available for discussion of these features, but the practical point that loss of body water and electrolyte leads to shock needs emphasis. Loss of extracellular electrolyte usually involves decrease in plasma volume and a tendency to lose plasma proteins. It is for this reason that patients suffering from dehydration must be given transfusions as well as salt solution. For the same reason a patient in dehydration must never be subjected to procedures leading to shock until his deficit of sodium chloride has been replaced, and frequently transfusions of blood are also indicated. This point is illustrated by the fact that the recent drop in operative mortality in such a surgical emergency as intussusception correlates with the preoperative care rather than with the time of operation. Decrease in glomerular filtration accounts for the poor renal function of dehydrated patients, and salt as well as water is required to restore urine volumes.

Experimental and clinical observations indicate that dehydration is usually accompanied by a relatively greater loss of sodium and chloride than of water and that this results in a decrease in the concentrations of extracellular electrolyte. In animals the maximal loss of extracellular electrolyte that is compatible with life is one third to one half of the total extracellular electrolyte. This is equivalent to 80 to 100 cc per kilogram of body weight of physiologic saline solution or some fluid more closely resembling interstitial fluid.

Table 4 shows the probable state of body water and electrolyte that results from the loss of about one third of the extracellular electrolyte without change in total body water. The figures are based on data obtained from analyses of cat muscle and represent fairly closely what occurs in many patients. Tables 3 and 4 should be compared to appreciate the deviations from normal. Note that the shift of water into the cells does not diminish the intracellular concentration of potassium as much as does the decrease in extracellular concentration of sodium.⁵ This representation conforms to direct

analyses of tissues⁶ and has been indirectly confirmed by other types of observation.¹³ The finding indicates that some intracellular compounds, presumably those combined with potassium, do not dissociate to the same degree under all conditions. In the schematic representation it was assumed that 10 mM (millimoles) of sodium was transferred from intracellular to extracellular fluids. Tissue analyses suggested but did not prove this type of reaction in cats subjected to depletion of extracellular electrolyte.⁵ The scheme indicates that about 600 cc of physiologic saline solution should correct all the defects in tissue composition if the kidneys function adequately.

Certain observations¹⁰ suggest that following loss of extracellular electrolyte the kidneys tend to restore the concentrations to normal by excreting water. In the above schema this could be done by the excretion of 0.6 kg of water. Theoretically this would leave intracellular fluids normal but reduce extracellular water to 1.9 instead of 2.07 kg. With small losses of extracellular electrolyte

in the present discussion to represent a disturbance in tissue composition. When the various items are left in the body in abnormal proportions, a disturbance in body water and electrolyte has developed.

As shown in Table 3, a considerable normal variation in intracellular electrolyte is indicated. Thus, if all intracellular sodium leaves the cells, an amount of sodium (54 mM) is made available to extracellular fluids that is equivalent to about one sixth of the total extracellular sodium. In terms of acid-base equilibrium this amount of sodium could increase the sodium available to form bicarbonate by an amount equivalent to three fourths of the normal sodium bicarbonate of extracellular fluids. On the other hand, if the muscle started with low intracellular sodium, increase in intracellular sodium to the usual higher figure would have a corresponding effect in decreasing extracellular sodium, especially that combined with bicarbonate. Both types of reaction probably take place especially in degrees not involving all the intracellular sodium. These small shifts of intracellular sodium, however, are

TABLE 4 The Extracellular and Intracellular Fluids in a Dehydrated 10-Kg Child *

*It is assumed that no water has been lost and that the loss of electrolyte is 87 mM of sodium and 66 mM of chloride; the composition of the intracellular fluid is based on analyses of cat muscle.

this type of reaction occurs, but with large deficits of sodium and chloride the kidneys excrete water slowly and tend to preserve volumes at the expense of concentrations.¹⁴⁻¹⁶

Dehydration may be caused by abnormal diuresis, —adrenal insufficiency, diabetes, hyposthenuric nephritis and so forth, —diarrhea, sweating or vomiting. Furthermore, localization of extracellular electrolyte at the site of trauma or a burn affects the rest of the body in much the same manner as does loss from the body. Each type of loss tends to have certain characteristic features. These have previously been adequately described.¹⁰⁻¹² For this reason the rest of the discussion will be concerned with intracellular changes.

CHANGES IN BODY FLUIDS INVOLVING INTRACELLULAR ELECTROLYTE

During starvation, fever and certain other disturbances, cellular structures may be consumed as a whole. In this case, nitrogen, potassium and phosphorus are excreted together with water in the proportions that make up the tissues consumed. This type of change leads to loss of body water and electrolyte, but the remaining tissues are relatively normal, and such losses are not considered

difficult to prove in patients, and considerable study will be necessary to determine the frequency and extent of such changes under various circumstances.

Studies have shown that practically all intracellular sodium is transferred to extracellular fluids in one type of acidosis. This observation was made in infants subjected to a procedure leading to retention of chloride without change in total body sodium.¹⁷ Further study will be necessary to determine how frequently a similar transfer occurs in other types of acidosis and whether other types of change in extracellular fluids can produce the same shift of sodium out of the cells. As long as the shifts of sodium in the cells are within the normal range, such deficits as develop involve only sodium and chloride and hence can be treated with sodium chloride and sodium bicarbonate.

Under a number of conditions potassium can be lost from the body in excess of the loss of nitrogen or phosphorus, thus leaving the cells relatively poor in potassium. This type of change in intracellular composition has been best demonstrated in skeletal muscle and occurs in the heart and brain, but has not yet been demonstrated in other tissues. Table 3 shows a fairly large normal variation of potassium,

but beyond this range the change is abnormal and sodium tends to replace potassium in almost equivalent amounts. As much as one half the muscle potassium may be replaced by sodium in experimental animals, and evidence is accumulating that similar if less marked changes can occur in human beings.

Table 5 represents the probable water and electrolyte of the body that result when about one third of the intracellular potassium is replaced by sodium and no gross change in extracellular fluids accompanies the change in intracellular electrolyte. Under these circumstances, intracellular sodium is equivalent to about two thirds of the total extracellular sodium. The concentration of serum potassium is represented as low since low serum potassium occurs frequently, but by no means always, when muscle potassium is deficient. Serum chloride is represented as low, and bicarbonate high, although this type of change is also not always present. The picture is probably exaggerated over the ones that are encountered clinically, but subsequent discussion

tions of sodium chloride and glucose while receiving no food by mouth.²⁴ On the other hand, potassium deficit may be produced through losses in the stools. Low serum potassium has been found in 2 cases of sprue, administration of potassium by mouth produced clinical improvement.²⁵ Such large stool losses of potassium in relation to nitrogen as were demonstrated many years ago²⁶ show that deficit of potassium must be an important feature of many cases of infantile diarrhea. I have studied a case of severe diarrhea in an infant that showed such retentions of sodium, chloride, potassium and nitrogen during recovery from marked dehydration and acidosis that the data can only be interpreted as indicating that a deficit of potassium was present before treatment. The data show that abnormal amounts of sodium had entered the cells to replace the deficit of potassium. The patient apparently developed acidosis because sodium went from the extracellular fluid to the cells and not because sodium was lost from the body. Hence the acidosis was chiefly dependent on the deficit of body potas-

TABLE 5 The Extracellular and Intracellular Fluids in a 10-Kg Child after Depletion of Potassium *

*It is assumed that some loss of intracellular water had occurred that the weight hence became 9.7 kg. and that the depletion of potassium was about one fourth of the low normal content. The changes in intracellular water were suggested from analyses of rat muscle.

shows that considerable deficit of potassium occurs clinically, and only further study can assay the frequency and degree of the deficit.

Loss of muscle potassium may occur from three causes. First, a negative balance of potassium develops from a discrepancy between the rate of intake and output. Since the stools and urine always contain potassium, a diet low in potassium produces deficit of muscle potassium with replacement by sodium. This was first demonstrated in growing rats,¹⁸ and the same condition was found independently in adult rats.^{8,19} The same abnormal composition of muscle can be produced on normal diets by increasing the rate of renal excretion of potassium. Desoxycorticosterone acetate has this effect to a marked degree.^{8,19,20} Adrenocortical extract, testosterone and estrogens exhibit it to a less degree.^{19,21} Some patients with Cushing's syndrome apparently develop potassium deficit. This is indicated by reports of cases showing high concentration of bicarbonate, high or normal sodium and low chloride and potassium in serum.^{22,23} The alkalosis and low chloride do not respond to sodium chloride but do respond to potassium salts. Renal loss of potassium can apparently also be excessive in patients receiving parenteral therapy with solu-

sium. This interpretation of the balance data assumes an abnormal intracellular fluid in the muscle such as is represented in Table 5. Such a state has been found by analyses of the muscle of an infant dying of diarrhea.⁷ In all the above types of potassium deficit, the changes in intracellular fluids are dependent on loss of body potassium.

A second type of deficit of intracellular potassium is apparently dependent on a changed equilibrium in intracellular fluids in states of marked alkalosis. This surmise was first suggested by observations on 2 patients suffering from a congenital defect in intestinal absorption leading to profound alkalosis as a result of loss of water, chloride and sodium in the stools.^{27,28} During the development of an extremely low serum chloride and an extremely high bicarbonate, more chloride was lost than sodium, and the changes in serum concentration demonstrate that sodium entered the cells and displaced equivalent amounts of potassium. The deficit of potassium developed owing to excretion in the urine in two periods and in the stools in one.²⁹ For this reason it seems likely that the potassium was freed from the cells owing to a disturbed equilibrium in the cells rather than to a necessity of the kidneys to excrete potassium instead of sodium. The suggestion

of a disturbed equilibrium in alkalosis tending to produce high intracellular sodium and low potassium has been confirmed by direct analyses of rat muscle following the production of alkalosis due to loss of chloride without sodium. After several days, this type of alkalosis leads to a change in muscle composition characterized by high intracellular sodium and low potassium.⁷ It is likely that the same reaction to alkalosis explains the muscle composition of rats kept for several days at a low atmospheric pressure.²⁹ Future investigations should show whether the same change in muscle composition occurs in some cases of pyloric obstruction. That such a change is likely is suggested by the relative ineffectiveness of treatment with sodium chloride in certain patients. If the loss of electrolyte were purely extracellular, sodium chloride would provide adequate treatment.

A third possible mode of development of relative deficit of potassium is suggested by observations in a patient receiving testosterone who showed low serum potassium levels and a greater retention of nitrogen relative to potassium than is ordinarily considered to be compatible with the formation of normal muscle.³⁰ The data suggest that deficit of potassium may develop during rapid storage of nitrogen, although the experiments are complicated by previous administration of desoxycorticosterone acetate.

Recognition of the above intracellular changes is bound to modify the concepts of treatment, but much work remains to be done before a practical guide can be given for the treatment of the disturbance of the intracellular fluids. In the space available a few obvious implications will be mentioned.

First, acidosis does not involve changes in extracellular fluids alone. The dose of bicarbonate should take this fact into account. To restore the concentration of serum bicarbonate, the concentration of bicarbonate must first be raised in the total extracellular fluid. The following formula calculates the amount necessary in millimoles of sodium bicarbonate or cubic centimeters of molar sodium lactate.

Extracellular water \times deficit of carbon dioxide = 0.2 body weight \times (25-CO₂) = mM sodium bicarbonate or cc molar sodium lactate,

when the body weight is expressed in kilograms and the carbon dioxide in millimoles per liter. If extracellular water is low, the necessary amount of sodium chloride and sodium bicarbonate together with water must be given to replace this deficit. This requirement is satisfactorily taken care of by physiologic saline solution in the amounts appropriate to the degree of clinical dehydration. If intracellular sodium has been depleted, this additional requirement must be administered before tissue electrolyte can become normal. Intracellular sodium in millimoles is equal to about ten times half the body weight. It is interesting that this analysis of the three sources of the deficit of sodium in acidosis

fits the frequently used formula for calculating the dose of sodium bicarbonate, namely,

Half body weight \times deficit of carbon dioxide = 0.5 body weight \times (25-CO₂) = mM sodium bicarbonate or cc molar sodium lactate,

where the body weight is expressed in kilograms, and the carbon dioxide deficit in millimoles per liter.

The implications of abnormally high intracellular sodium are different, since this implies a deficit of potassium that renders the high intracellular sodium unavailable to extracellular fluids until potassium is restored. Thus, in acidosis the dose of bicarbonate may be the same in a patient with potassium deficiency, as is indicated above, except that as potassium is retained, a tendency to alkalosis may develop. On the other hand, a combination of the chlorides and bicarbonates of both sodium and potassium may turn out to be the most effective treatment of cases of acidosis with potassium deficit.

In the alkalosis of certain cases of Cushing's syndrome, the abnormal serum composition tends to persist until potassium salts are administered.³¹ The refractoriness of some cases of pyloric obstruction to sodium chloride suggests an analogous state of deficit of potassium. Future research may demonstrate that the chlorides of both sodium and potassium are indicated in the treatment of certain cases of alkalosis.

In any case, deficits of both potassium and sodium chloride are factors in disturbed balance of water and electrolyte requiring practical as well as theoretical consideration. Moreover, deficiency of body potassium is known to be an extremely serious condition, since it produces necrosis of the heart muscle³² and under unusual circumstances muscular paralysis, which is relieved by potassium.³³ There can be no doubt that the treatment of Addison's disease with desoxycorticosterone acetate has produced heart lesions and death from cardiac failure, but moderate deficits of potassium may be relatively harmless. Since most foods are rich in potassium, most patients tend to recover from potassium deficiency when they can eat. Others require specific treatment with potassium salts.

Administration of potassium salts must be undertaken with caution until more quantitative facts are available concerning the amount of the deficit, the cases requiring treatment and the effect of the administration of potassium salts. Caution is necessary particularly for parenteral therapy, since a rise of extracellular potassium concentration to about 10 mM per liter causes heart block. Potassium salts can be given by mouth with little hazard if renal function is good. Future study will doubtless show a fairly wide field for potassium therapy.

SUMMARY AND CONCLUSIONS

The disturbances in water and electrolyte balance are discussed with emphasis on the changes in intracellular electrolyte. There is a normal variation

intracellular sodium equivalent to about one sixth of total extracellular sodium. This intracellular sodium is available to extracellular fluids in some cases of acidosis.

If potassium is lost from muscle cells beyond a limited amount, sodium tends to enter the intracellular fluid in about equivalent amounts. This type of exchange can involve almost half the muscle potassium, and under these circumstances intracellular sodium is equal to over half the total extracellular sodium.

This replacement of muscle potassium by sodium occurs as the result of potassium loss owing to diarrhea, abnormal renal excretion as a result of the presence of certain steroids (desoxycorticosterone and those concerned with hyperadrenalism) and following deficient intake.

Potassium probably tends to be displaced by sodium in marked alkalosis and perhaps during rapid storage of nitrogen under the influence of testosterone.

It is pointed out that transfer of extracellular sodium to intracellular fluids tends to produce acidosis or to decrease alkalosis and that the reverse process occurs when intracellular sodium enters extracellular fluids. The implication of these changes regarding therapy are briefly discussed.

MASSACHUSETTS MEDICAL SOCIETY

PROCEEDINGS OF THE EXECUTIVE COMMITTEE OF THE COUNCIL

Held in Lieu of the Annual Meeting of the Council, May 23, 1945

THE meeting was called to order by President Bagnall on Wednesday, May 23, 1945, at 10 30 a m, in Sprague Hall, 8 Fenway, Boston

The following members of the Executive Committee were present

President Elmer S Bagnall
President-Elect Reginald Fitz
Secretary Michael A Tighe
Treasurer Eliot Hubbard, Jr

Barnstable William D Kinney
Berkshire Isaac S F Dodd
Bristol North William H Allen
Bristol South Edwin D Gardner
Essex North Frank W Snow
Essex South Walter G Phippen
Franklin William J Pelletier
Hampden William A R Chapin
Middlesex East Edward M Halligan
Middlesex North William F Ryan
Middlesex South Dwight O'Hara
Norfolk Charles J Kickham
Norfolk South Henry A Robinson
Plymouth Peirce H Leavitt
Suffolk Donald Munro
Worcester Ralph S Perkins
Worcester North C Bertram Gay

The following chairmen of committees were present Francis C Hall, Roy J Ward, Howard F Root, Frank R Ober, Charles F Branch, Z William Colson, Richard M Smith, Arthur W Allen, W Richard Ohler, Albert A Hornor, William E Browne, Daniel B Reardon, Charles E Mongan, Nathaniel W Faxon, Guy L Richardson, John J Dumphy, Daniel J Ellison, Arthur L Watkins, Robert T Monroe, John Fallon, Roy J Heffernan, Joseph Garland, Leland S McKittrick, Charles F Wilinsky, and Ralph R Stratton

The President, in opening the meeting, announced that the Executive Committee was holding it in lieu of the annual meeting of the Council, the petition to hold the latter meeting having been denied by the Office of Defense Transportation. He said that the personnel of the gathering was made up of the members of the Executive Committee, chairmen of committees and the secretary of the Committee on Public Relations. He suggested that all present be permitted to participate in the discussions attending this meeting and that this privilege be granted by the unanimous consent of the Executive Committee. This consent having been obtained, he invited and urged all present to participate.

He ruled that only members of the Executive Committee would be permitted to vote.

The Secretary announced that the minutes of the meeting of the Executive Committee, held on December 27, 1944, and January 31, 1945, had been sent to each member. He moved their acceptance. This motion was seconded by Dr Frank R

Ober, Suffolk, and it was so ordered by vote of the Committee.

The Secretary offered the record of the Council meeting held on January 31, 1945, as published in the *New England Journal of Medicine*, issue of May 17, 1945. Its acceptance was moved by Dr Edwin D Gardner, Bristol South. This motion was seconded by Dr Eliot Hubbard, Jr, Middlesex South, and it was so ordered by vote of the Committee.

REPORT OF THE TREASURER

This report (Appendix No 1) was offered by Dr Hubbard. He spoke of certain corrections that he wished to make in this report as published in the circular of advance information. He moved the adoption of the report subject to these corrections. This motion was seconded by Dr William H Allen, Bristol North, and it was so ordered by vote of the Committee. (The corrections referred to have been made in the appendix as published.)

REPORTS OF COMMITTEES

Auditing Committee — Dr Z William Colson, Essex North, chairman

This report, which was offered by the chairman, is as follows:

The Auditing Committee appointed the firm of Hartshorn and Walter, accountants and auditors, to audit the books and accounts of the Massachusetts Medical Society. These accountants have submitted an analysis of the revenues and expenses of the Society and a balance sheet of the condition of the Massachusetts Medical Society as of December 31, 1944. The Auditing Committee took cognizance of the fact that these public accountants had been repeatedly chosen in previous years and had executed their functions satisfactorily and that any change in the public accountants would have necessitated a considerable amount of extra work for the Treasurer, which seemed inadvisable in a war year.

The report submitted by Hartshorn and Walter was examined by the Auditing Committee and found to be comparable to those of previous years.

According to the by-laws, the duties of the Auditing Committee include verification of the accountant's examination. No investigation other than an examination of the accountant's report was made, this liberal interpretation of the Auditing Committee's function being consistent with precedent.

(Owing to the need for conserving space because of the shortage of paper, the report of Hartshorn and Walter is not reproduced in the appendices. All significant figures are given in the Treasurer's Report, and detailed information, including the list of securities held, may be obtained from copies of the report on file in the Treasurer's office.)

Dr Peirce H Leavitt, Plymouth, moved the acceptance of the report. This motion was seconded

by Dr Allen, and it was so ordered by vote of the Committee

Committee on Nominations — Dr Ralph R Stratton, Middlesex East, chairman

In reporting for this committee, Dr Stratton presented the following list of officers for the year 1945-1946

President Reginald Fitz, Suffolk
President-Elect Dwight O'Hara, Middlesex South
Vice-President William Jason Mixer, Suffolk
Secretary Michael A Tighe, Middlesex North
Treasurer Elhot Hubbard, Jr, Middlesex South
Assistant Treasurer Norman A Welch, Norfolk
Orator Frank H Lahey, Suffolk

Dr Stratton moved the acceptance of the report. This motion was seconded by Dr William A R Chapin, Hampden, and it was so ordered by vote of the Committee

The President asked if there were any nominations from the floor. There were none

Dr Stratton moved that the nominations be closed. This motion was seconded by Dr. Leavitt and it was so ordered by vote of the Committee

Dr Stratton moved that the Secretary cast one ballot for the slate as submitted by the Committee on Nominations. This motion was seconded by Dr Allen and it was so ordered by vote of the Committee

The President, after announcing that the Secretary had complied with this direction, declared the officers listed above elected

Committee on Membership — Dr Harlan F Newton, Suffolk, chairman

In the absence of the chairman, the report (Appendix No 2) was offered by Dr Leavitt, a member of the Committee on Membership

Dr Leavitt, in submitting the recommendations of his committee, as published in the circular of advance information, said that the committee wished to amend these recommendations by adding the name of Dr Harry H Butler (Norfolk), 48 Winchester Street, Brookline, to those recommended for reinstatement. He moved the adoption of the committee's recommendations as amended. This motion was seconded by Dr Charles J Kickham, Norfolk, and it was so ordered by vote of the Committee

Dr Kickham, at this point, asked permission of the chair to direct certain questions to Dr Leavitt in the latter's capacity as a member of the Committee on Membership. Dr Kickham said he was making the request at the direction of the councilors of the Norfolk District. This permission having been granted by the chair, Dr Kickham addressed the following questions to Dr Leavitt

1 Does the Committee on Membership feel that the local committees on membership are superfluous and that, therefore, it would be wise to have a change in the by-laws whereby the local committees would be omitted entirely?

Dr Leavitt answered, 'By no means'

2 Does Dr Leavitt, as a member of the Committee on Membership, feel that, in the procedure that has been followed to date, all due care has been taken in regard to applicants for membership?

Dr Leavitt replied in the affirmative

Dr Donald Munro, Suffolk, moved that the President appoint a committee to study the by-laws with the end in view of possibly revising the method by which candidates are admitted to membership in the Society. This motion was seconded by Dr Ober

In support of his motion, Dr Munro said that, when the present by-laws were in the stage of discussion, there was considerable debate whether or not it was advisable to give the Committee on Membership the power of vetoing the action of local committees. He added that it was finally decided that it was a good thing to do inasmuch as it would offer protection to local committees and that it was for this reason that certain provisions having to do with the admission of applicants were finally adopted. Dr Munro added that these certain provisions apparently were having some unexpected side effects, which were not anticipated at the time of their adoption

Dr William E Browne, Suffolk, asked how this proposed committee was to be constituted. Dr Munro replied that that should be left to the President

Dr Ober said that local committees should have in their possession the same information about a candidate as is available to the Committee on Membership

Dr Bagnall emphasized what Dr Munro said in respect to the intent of the discussions that preceded and the spirit that prevailed in adopting the present provisions of the by-laws

Dr Munro's motion was adopted by vote of the Committee

At that point in the meeting, no member of the Executive Committee being present from Essex South, the President exercised his prerogative under the by-laws and appointed Dr Walter G Phippen to serve in that capacity

Committee on Arrangements — Dr Roy J Heffernan, Norfolk, chairman

The report, which is as follows, was offered by the chairman

During the fall and winter months, a number of meetings were held to prepare for the 1945 annual meeting. Our aim was to provide a program that would cover the various fields of medicine and surgery, keeping always in mind the needs of the general practitioner. We were extremely fortunate in these busy times in receiving acceptances from many well-known authorities. The prospectus included three representatives from the Surgeon-General's Office and the director of the Army Medical Museum besides physicians from the Mayo Clinic, the Walter Reed Hospital, the University of Michigan and many eminent speakers from our own state

Our sale of booth space again showed an improvement, as \$10,965 worth of space had been reserved by the exhibitors. Of this amount, \$6630 had actually been paid to the treasurer of the Society. Mr. Robert Boyd had excelled his previous excellent record in this department. All the signs and portents indicated that the annual meeting would be one of the best in the history of the Society.

But, as the canny Scottish bard had it, "The best laid schemes o' mice and men gang aft a-gley."

We received a directive from the Office of Defense Transportation dated January 11, soon followed by another dated January 22, 1945. These stated in effect that no meetings or conventions could be held without special permission, if they were attended by more than fifty persons who had to use other than local transportation facilities.

It was obvious from these mandates that we had two courses open to us. One was voluntarily to cancel the meeting, and the second was to apply for permission to hold it. The committee met jointly with the officers of the Society on February 21, 1945, to discuss this matter. At that time we knew that the medical societies of Rhode Island and Delaware had been granted permission to hold their annual meetings.

At this conference the following facts were carefully weighed and considered: the heavy demands on the physicians' time and energy during the war leave very little opportunity for postgraduate study, the global nature of the conflict in which our armed forces are engaged raises the possibility that the returning veteran may introduce diseases unusual to our communities and unfamiliar to the practitioner of medicine, the health of the large number of workers in defense industries in the Commonwealth could be best maintained by physicians well informed in the latest developments in medicine, and the large attendance on the part of medical officers of the military services at previous wartime meetings and the enthusiastic comments of these doctors and their superior officers seemed to indicate that the meeting was of considerable value to them. These and other important considerations convinced the committee that we should apply to the Office of Defense Transportation for permission to hold our meeting as planned.

This application was forwarded to Washington on February 24, 1945. The reply, dated March 9, was received on March 12, and we learned that permission to hold the meeting had been denied.

It was obvious that the committee had no choice but to cancel all arrangements, notify the speakers and return the money to the exhibitors. These actions have now been consummated.

Dr. Heffernan moved the acceptance of the report. This motion was seconded by Dr. Munro, and it was so ordered by vote of the Committee.

Committee on Public Relations—Dr. Albert A. Hornor, Suffolk, secretary.

This report (Appendix No. 3) was offered by Dr. Hornor.

It spoke of a review by the committee of the activities of the Committee on Postwar Planning, as presented by Dr. Howard F. Root, and of the desire of the Committee on Public Relations to support Dr. Root's committee in every way possible.

The work of the Subcommittee on Labor and Industry was reviewed, and the thought expressed that this subcommittee should pursue its activities farther.

The activities of the Subcommittee on Public Information were reviewed, and its recommendations approved.

The report spoke of certain directions that were given to the Subcommittee on Tax-Supported Medical Care and of the approval that had been

given to this subcommittee's work along these lines—with two members of the Committee on Public Relations dissenting in the matter of this approval. The report called attention to the fact that the reports of these three subcommittees would be presented later in the meeting.

The report spoke of a joint program that was about to be entered into by the Red Cross and the Massachusetts Department of Public Health where by the Red Cross would continue to collect blood after the war and turn it over to the Department of Public Health for processing and distribution without charge, in much the same manner as other biologicals are distributed by this department.

Dr. Hornor said that the committee approved of this plan and recommended that the Executive Committee do likewise.

Dr. Hornor moved the acceptance of the report and the adoption of the recommendation contained therein. This motion was seconded by Dr. Frank W. Snow, Essex North, and it was so ordered by vote of the Committee.

Dr. Chapin asked if it was necessary to read reports that were contained in the circular of advance information. The President replied that such reports could be submitted by title only.

Subcommittee on Labor and Industry—Dr. Daniel B. Reardon, Norfolk South, chairman.

This report (Appendix No. 4) was offered by Dr. Reardon. It spoke of certain conferences that had been held by the subcommittee with labor, as represented by the CIO and of the Massachusetts branch of the American Federation of Labor, and with industry, as represented by the Associated Industries. These conferences had to do with the matter of the distribution of medical care. The report summarized the desires of the CIO as being comprehended in the following language: adequate medical care at a price the worker is able to pay. The representatives of the American Federation of Labor believed that their needs could best be met by private insurance carriers, provided the entire cost of such insurance was carried by industry.

The group from the Associated Industries thought that the problem should be defined as twofold: the economic loss to the individual caused by wage stoppage when that individual is ill and the loss due to medical-care costs. This group believed that the first was a social problem, which should be met by legislation. It seemed to be the viewpoint of the industrialists present that industry should not be asked to bear the medical-care costs, beyond certain managerial expenses that might be incidental to any insurance plan set up and paid for by the workers themselves.

Dr. Reardon moved the acceptance of the report.

This motion was seconded by Dr Phippen, and it was so ordered by vote of the Committee

Subcommittee on Public Information—Dr John Fallon, Worcester, chairman

This report, which was offered by the chairman, is as follows

The chief function of your committee has been the organization of the part to be played by the Society in Massachusetts Health Week. Health Week arose from the suggestion of the Massachusetts Dental Society, through its president's assistant, to Governor Tobin that Health Day, normally observed during the first week of May, be elaborated to Health Week. The Governor approved and invited the Massachusetts Medical Society to participate.

The resulting conferences of your committee with His Excellency, the Governor, members of his staff, with officers and representatives of the Massachusetts Dental Society, Massachusetts Hospital Association, Blue Shield, Blue Cross, Blue Triangle, Massachusetts Department of Public Health and Massachusetts Central Health Council and with professional publicists, newspaper men, radio men and officers of this society led to the following commitments

Health Week was advanced from the first to the second week of May (May 6-12) so as to include National Hospital Day (a fixed date, Florence Nightingale's birthday, May 12)

The above-named individuals and agencies severally contributed to Health Week, as a public service and without recompense, fundamental information, elaboration of this into copy for public presentation, newspaper space and radio time

The share of the Massachusetts Medical Society was the furnishing of a list of timely medical subjects and a list of doctors qualified in these subjects for interview by press and radio. From such interviews professional publicists prepared final newspaper and radio copy, subject to editing by this committee. Such copy was distributed to editors and radio stations in each district by the district member of the Committee on Public Relations. As a preliminary step the Massachusetts Medical Society broadcast from a Boston radio station, WORL, on Sunday afternoon, April 22

In its conversations with the public men and publicists named above, your committee made certain observations, which it presents to the Executive Committee

It deduces that the Society should do more than it has in the past to inform the public about medicine and about itself and that it should try to correct certain public misconceptions

It believes that publicity is a technical and specialized field and that it would be more practical for a professional publicist, directed by doctors, to handle the Society's publicity than for a busy doctor to attempt to learn the technique of publicity. It calls attention to the wisdom of a similar course in a similar case: the management of the Society's funds by professional investment counsel

It believes that publicity for many of the health organizations in Massachusetts, foremost of which is this society, might jointly be handled by one central agency. It has appointed a subcommittee to explore this possibility with the Massachusetts Central Health Council

Stories "planted" as news with editors or commentators and therefore subject to editing, may be so changed by the custom of writing for the public taste and by the exigencies of available space and nonmedical editing as to lose point, accent or even truth

Paid-for copy is printed or broadcast unaltered and uncut.

There is ample statistical proof that paid newspaper and radio advertising is the best way of presenting information to the largest number of people. The Blue Shield, Blue Cross and Massachusetts Department of Health have found this true for the kind of information that they furnish the public. Incidentally, the Department of Public Health has found that, of all its methods of bringing information to the public, the method eliciting least response is the pamphlet written and distributed by the department itself

The committee is exploring possibilities of co-operation in the dissemination of health information with agencies such as the New England Council, foundations and so forth. With such conclusions in mind, the committee recommends

1 That the Executive Committee approve payment by the Society for the dissemination of medical information to the public through the medium of newspapers, magazines, radio, cinema or other means

2 That the Executive Committee approve a budget of \$1000 for the Committee on Public Information for administrative expenses

In commenting on this report Dr Fallon said that from the standpoint of getting health information to the public the observance of Health Week could not be considered a success. He pointed out that Germany collapsed the same week and that, as a consequence of this fact, newspaper space and radio time were not so available as they might otherwise have been. He said that one hundred and ten items concerning Health Week did appear in newspapers and that there were four broadcasts. He added that the large amount of material collected under the project as planned need not, however, be lost. It might be used subsequently

Regarding whether or not our Society needs to have its works further publicized, Dr Fallon said his committee believes that this is a subject it should be permitted to investigate further. He said that there seems to be a rather general feeling that the Society's present public relations can be improved on

Dr Fallon said that the following line, which appears in the report, is probably its most important part, "Paid-for copy is printed or broadcast unaltered and uncut," while adding that this was particularly important to the scientifically minded. He said he did not lose sight of the fact that some particular message that the Society might desire to get over to the public by means of paid advertising might need the touch of those more skilled than are physicians in such matters. The final decision of what would appear, however, should rest with the Society

Dr Fallon said that there was ample statistical proof that newspaper and radio advertising is the best way of presenting information to the largest number of people. He added that this was the experience of the Blue Shield, Blue Cross and the Massachusetts Department of Public Health

He spoke of a radio program initiated by the Michigan State Medical Society, in which program this society had invited us, together with sixteen other states, to participate. He referred to a sample recording of the program that the committee heard, and added that the members of the committee considered it a "little too blunt for their palates"

Dr Fallon moved the acceptance of the report and the adoption of the recommendations contained therein. This motion was seconded by Dr Peirce Leavitt

Dr Reardon said that newspaper and radio

publicity were expensive procedures. He asked Dr. Fallon if his committee had any idea concerning the amount of money the Society should appropriate every year for this purpose.

Dr. Fallon, in replying to Dr. Reardon, said he was in agreement with the latter that this type of publicity was expensive. He added, however, that the moneys asked for in the committee's second recommendation were not to be spent in publicity but rather for the purpose of enabling the committee further to study public-relations methods. Paid space might not often be needed, but he thought it advisable to have the Executive Committee pass on the principle involved.

Dr. Hornor asked if the Society's present tax-exempt status would be affected by engaging in such activities. Dr. Fallon replied that this phase of the subject had been discussed with Mr. Robert G. Dodge, attorney.

He read the following excerpt from a letter from Mr. Dodge:

I see no grounds on which the Massachusetts Medical Society could by advertising of any kind lose its exemption from income taxation.

Even if you should advertise, for example, a statement of the position of the Society with regard to the Wagner Act, that would make no difference, so far as taxation is concerned.

Dr. Browne said that, if and when the Society is finally committed to the policies outlined by the committee, it should spend sufficient moneys to do the job properly.

Dr. Fallon's motion to accept the report and approve the recommendations was adopted by vote of the Committee.

The Committee recessed at 1:00 p.m. and reconvened at 1:45 p.m.

Dr. Bagnall read the President's Report on the State of the Society. (This report is published in full elsewhere in this issue of the *Journal*.) At its conclusion, Dr. Bagnall was greeted with loud applause.

Committee on Tax-Supported Medical Care — Dr. John J. Dumphy, Worcester, chairman.

This report, which was presented by the chairman, is as follows:

The Committee on Tax-Supported Medical Care met with the Commissioner of Public Welfare, Mr. Arthur Rotch, on April 18, 1945.

Two subjects were taken up — first, the payment of physicians caring for welfare patients in unstaffed hospitals, and, second, the payment of physicians taking care of all welfare patients.

With regard to the first question, Mr. Rotch stated that he is prepared to recommend payment of present Blue Shield rates for surgical patients cared for by physicians in unstaffed hospitals. For medical cases, the payment would be four dollars for the first day and two dollars per day thereafter for a period not to exceed two months or one hundred and fifty dollars. For illness longer than two months requiring hospital care, each case would be considered separately.

With regard to the question of payment of physicians on all welfare patients, Mr. Rotch stated that, under the

present system of medical practice whereby free services are available, as the state commissioner, he must avail himself and the Commonwealth of free services where they are available.

The committee recommends that the Council approve the policy of paying physicians in unstaffed hospitals for the care of welfare patients at the following rates for medical cases, four dollars for the first day and two dollars for each succeeding day for a period not to exceed two months or a total of one hundred and fifty dollars, and for surgical cases, the present Blue Shield rates prevail. For welfare patients in staffed hospitals that they continue to be cared for as staff patients without charge by attending staff physicians.

In commenting on the report Dr. Dumphy said that Mr. Ray Long, Commissioner of Veterans and Pensions, was much disturbed by the great variation in doctors' bills for handling the same type of service and that the latter had asked that the Blue Shield rates be made the standard for payment of surgical fees. He said his committee was in agreement with Mr. Long on this proposition. He referred to that part of the report of the Committee on Public Relations which directed his subcommittee to approach Mr. Rotch, Commissioner of Welfare, and ascertain from the latter whether or not he, too, would be willing to accept the Blue Shield rates as the standard for the payment of surgical fees for services rendered to welfare cases in unstaffed hospitals. Dr. Dumphy explained that at the time his subcommittee received this directive from the Committee on Public Relations, an agreement had been entered into whereby the Welfare Department would pay three quarters of the rates established by the Blue Shield schedules for surgical services rendered such cases. He added that Mr. Rotch had accepted this latest proposition and he referred to a letter that he had received from him, a copy of which was in the possession of each member of the Executive Committee.

Dr. Dumphy then referred to a further directive that his subcommittee had received from the Committee on Public Relations, namely, that the Commissioner of Welfare should be approached with the end in view that these same regulations should equally apply to staffed hospitals. To this proposition Dr. Dumphy said Mr. Rotch could not agree.

Dr. Dumphy now moved the acceptance of the report and the adoption of the recommendation contained in its last paragraph. This motion was seconded by Dr. Munro and it was so ordered by vote of the Committee.

(For schedule of fees under this heading, refer to Appendix No. 5.)

At that point in the meeting Dr. Bagnall spoke of a visit that he made to Michigan on April 27 and 28, 1945. He said he made the visit in consequence of an invitation issued to him and to the presidents of several other state medical societies by the president of the Michigan State Medical Society.

The following resolution was adopted by this group so gathered:

BE IT RESOLVED, That this group expresses its continued loyalty to the American Medical Association, That it is the duty of the various state medical societies to advise the American Medical Association through its Council on Medical Service and Public Relations, of their wishes in regard to national health legislation, That the presidents of the several states and District of Columbia medical societies or their representatives act as a permanent committee immediately to set up drafting panels in each state for this purpose, That states not represented here today be invited and encouraged to join in this work, and That the president of the Michigan State Medical Society be designated as temporary chairman of this committee to facilitate its activities

A second resolution, which is as follows, was also adopted

BE IT RESOLVED, That the president of the Michigan State Medical Society be authorized to appoint a committee to study the feasibility of commercial radio broadcasting as related to the various states here represented in co-ordinating and co-operating in the development of such programs as presented today (April 27) and to make recommendations for the best manner of carrying out such a program

Dr Bagnall said that Dr E J McCormick of Toledo, a member of the Council on Medical Care and Public Relations of the American Medical Association, and the secretary of that council were present at the meeting and that they together with the 18 states represented unanimously approved the resolutions

In referring particularly to the planning committees mentioned in the first resolution Dr Bagnall said that these committees should consider what might be strategic and desirable in the way of legislation to put before Congress, that their plans will then be processed through a central committee, elected from these eighteen states and from any other state that might care to come into the plan, and that the agreed-on action be then processed through the Council on Medical Service and Public Relations of the American Medical Association for reference to the House of Delegates of the American Medical Association Dr Bagnall suggested that the Committee on Public Relations of the Massachusetts Medical Society might be designated as the planning committee under this title It was so moved by Dr Kickham This motion was seconded by Dr I S F Dodd, Berkshire

Dr Hornor asked for a definition of panel planning Dr Bagnall said that there were many influential people who believe that some legislation relating to medical care will come out of Congress before many years and that the medical societies should have a share in planning it He added that the purpose of the panel planning committee was to bring the thinking of the several states to the attention of the Council on Medical Care and Public Relations of the American Medical Association

Dr Kickham's motion was adopted by vote of the Committee

Committee on Legislation — Dr William E Browne, Suffolk, chairman

This report (Appendix No 6) was presented by the chairman who moved its approval This motion was seconded by a member of the Committee

Dr Reardon asked if he had correctly heard Dr Browne say that under one of these bills an osteopathic diplomate would have the privilege of practicing medicine in Massachusetts without taking the examinations of the Board of Registration in Medicine Dr Browne replied in the affirmative saying that such a person would have the privilege of practicing medicine in Massachusetts provided he holds a certificate from the national osteopathic examiners, provided he is a graduate of a recognized school of osteopathy, provided his school is approved by the Massachusetts Approving Authority, provided he presents himself to the Massachusetts Board of Registration in Medicine, and provided that this latter board may, in its discretion, grant him a license to practice medicine He added that there are six recognized schools of osteopathy in the country

In answer to a question by Dr Hornor, Dr Browne said that the practice of medicine had never been defined by the Massachusetts Laws

Dr Kickham said he had been requested by the Norfolk District Medical Society to ask on what grounds the so-called "reportable cancer bill" had been approved by the Committee on Legislation He added that as his district had the facts this bill not only served no good purpose but might do much harm

Dr Browne replied that this bill had been discussed in the Council meeting held on January 31, 1945, and that he said, at that time, that although his committee had not had sufficient time to really study this bill, it probably would approve it in principle and that there was no remonstrance As time went on, he added, it became apparent that those who knew much about cancer favored the bill, finally, he said that this bill had been considered by the Executive Committee of the Committee on Legislation several days previously and that no opposition to it was apparent at that time He pointed out that the representative from the Norfolk District Society sat in this meeting Dr Humphrey McCarthy, Norfolk, said that he did present Norfolk's attitude toward this proposed legislation at the meeting referred to by Dr Browne and that nobody else present opposed the legislation

Dr Browne's motion to approve the report was so ordered by vote of the Committee

Committee on Information Bureau — Dr Walter G Phippen, Essex South, chairman

This report, which was offered by the chairman is as follows

Since the last meeting of the Council the Bureau of Information has continued to function and grow. Our mailing list for the *Bulletin* has grown from 175 to 194. The number of requests for information over the phone or by letter during the period from January 23 to March 1, has been 96 compared with 75 over the longer period before. These requests were almost all for information concerning operations or for the *Bulletin*. There have also been over 30 requests for various information, such as refresher courses, and so forth, by persons at the office. Since the last report also we have added the Boston Dispensary to our list of hospitals sending us daily information, bringing the number up to twenty-two, including the Lahey Clinic. As this is the number we originally planned to cover, we are quite satisfied.

The committee believes that the Bureau is now well organized and working satisfactorily and that its future development will be very much a part of the postwar planning activities of the Society, it therefore recommends that this committee be discharged and that the Bureau be transferred to the Subcommittee on Postgraduate Education.

Dr Phippen moved the acceptance of the report and the adoption of the recommendation contained therein. This motion was seconded by Dr Leavitt, and it was so ordered by vote of the Committee.

Committee on Postwar Planning — Dr Howard F Root, Suffolk, chairman

This report (Appendix No 7) was offered by the chairman. It spoke of the result of a questionnaire that had been sent to doctors in the armed services concerning their future educational needs. The emphasis placed by the doctor, particularly in the younger group, was on the necessity of additional clinical training. The report went on to say that at least 12,000 hospital residencies in this country must be available if the needs of the returning doctor are to be met. The report continued to say that half this number are now available and that if the need is to be met, hospitals that have never had residencies must establish them.

The following two paragraphs are quoted from the report:

The returns from this questionnaire indicate how fully the recent graduate in medicine appreciates the inadequacy of his training, particularly along clinical lines. It is not sufficient to dismiss this as one of the exigencies of the war. If the same high standards of medical care to which the American people have been accustomed are to be maintained, notice must be taken of the inadequacy in preparation which looms large in the doctor trained in wartime, and every effort bent toward its relief.

The Postwar Planning Committee of the Massachusetts Medical Society believes that the hospitals of the Commonwealth can and should play a most important part in any program directed toward that end.

Dr Root spoke of the steps that the Subcommittee on Hospitals was taking to acquaint hospitals of Massachusetts with their opportunities along these lines. He added that on June 20, 1945, under the auspices of this subcommittee, a meeting was to be held with hospital representatives for this purpose. The report spoke of the interest that many doctors in the service showed in industrial medicine. The report called for an expansion of the Bureau of Information.

The report emphasized the necessity of the Society's being able and ready to assist the returned doctor in his relocation problems, and in respect to this Dr Root urged the district societies to return completed the questionnaire sent out by the Bureau of Information of the American Medical Association.

Dr Phippen moved the acceptance of the report. This motion was seconded by Dr C Bertram Gay, Worcester North.

At this point, the Secretary said that twelve of the districts (Barnstable, Berkshire, Bristol North, Essex North, Hampden, Hampshire, Middlesex North, Norfolk, Norfolk South, Plymouth, Suffolk and Worcester) had returned completed the questionnaire referred to by Dr Root. He urged the other districts to take this matter very much to heart.

Dr Phippen's motion was adopted by vote of the Committee.

Committee on Ethics and Discipline — Dr Ralph R Stratton, Middlesex East, chairman

The report (Appendix No 8) was offered by the chairman, who moved its acceptance. This motion was seconded by Dr Chapin.

In commenting on the report, Dr Stratton spoke of how time-consuming was the work of his committee, of the pains that had to be taken in the presentation of cases, of interviews that had to be held, of letters that had to be written and of files that had to be consulted.

In speaking of the last case mentioned in the report, he said that, although the offense was serious, the accused, who was found guilty, was let off with a severe admonition by the President, the committee taking note of the fact that this was the first time this physician had been before it. The motion to accept the report was adopted by vote of the Committee.

Committee on Medical Defense — Dr Arthur W Allen, Suffolk, chairman

This report, which is as follows, was offered by Dr Edwin D Gardner, Bristol South, in the absence of Dr Allen.

At this time, we have eleven cases pending trial. During the past year, three cases have been disposed of satisfactorily. We have acquired four new cases during the year.

Most of these suits are brought on very little evidence of malpractice and for this reason a judgment is rarely given against our fellows. Many of the suits never come to trial. There are, however, necessary legal expenses associated with these cases, the total bill for legal services during the year 1944 being \$853.03.

Dr Gardner moved the acceptance of the report. This motion was seconded by Dr C Bertram Gay, and it was so ordered by vote of the Committee.

War Participation Committee — Dr Guv L Richardson, Essex North, chairman

The report, which is as follows, was offered by the chairman

Since the last Council meeting, the activities of this committee have been concerned with assisting the Office of Price Administration in their relations with physicians. So far as we can determine, controversial matters have been adjusted satisfactorily to all concerned. The OPA asked that three additional local medical advisory committees be appointed, one for Lowell, one for Quincy and one for Holyoke. The committee in Lowell, under the chairmanship of Dr Daniel J Ellison, has already been set up. The others are in the process.

Dr Richardson moved the acceptance of the report. This motion was seconded by Dr W H Allen, and it was so ordered by vote of the Committee.

Medical Advisory Committee to the Regional OPA — Dr Joseph Garland, Suffolk, chairman

This report, which is as follows, was offered in the absence of Dr Garland by the Secretary

The duties of this committee have not abated since its last report and perplexing problems continue to present themselves. These are augmented by the fact that stricter rationing has been necessary this spring and will presumably last for an indefinite period, and the number of applications for increased rations is steadily increasing.

It seems still apparent that many physicians have not availed themselves of the opportunities offered to understand the rationing problem and to co-operate in the attempts that are being made to solve it. Valuable assistance continues to be given in selected communities by the local war-participation committees, acting as medical advisory committees.

The Secretary moved its acceptance. This motion was seconded by Dr Gardner, and it was so ordered by vote of the Committee.

Committee on Society Headquarters — Dr Frank R Ober, Suffolk, chairman

The report, which was offered by Dr Ober, outlined two plans by which the headquarters might be improved to serve better the purposes of the Society. Although the discussion indicated that the Committee favored Plan Two rather than Plan One, it was the consensus that more detail should be supplied by the Committee on Headquarters before any final action was taken.

It was moved by Dr Phippen and seconded by Dr Munro that the Committee tentatively approve Plan Two and direct the Committee on Society Headquarters to secure such options as are necessary for its realization. This motion was adopted by vote of the Committee.

Committee on Medical Education — Dr Robert T Monroe, chairman

In the absence of Dr Monroe, the Secretary offered the following report, which had been prepared by the former

At the request of the secretary of the Society, our committee has considered the problem arising under the G I Bill of Rights in regard to postwar training of veterans in the healing arts. The former expressed the fear that, unless our committee gave this matter some attention, the veteran might not receive in quality the training to which he was entitled.

The committee found that the Veterans' Bureau has no choice but to accept the list of schools for the training of veterans in the healing arts, under the G I Bill of Rights, supplied by the Board of Collegiate Authority of the Massachusetts Department of Education.

The committee chairman met with Mr F G Nichols, of the Board of Collegiate Authority, Mr Herbert A Dallas, of the State Division of Vocational Rehabilitation, and Dr Joseph H Shortell, chairman of the Massachusetts Medical Society's Committee on Rehabilitation. The committee has offered its services to Mr Nichols in advising him as to the qualifications of schools of medicine, nursing, physiotherapy, laboratory technicians, x-ray technicians and so forth. This offer has been accepted.

It may be desirable also for us to offer to veterans, through the Veterans Administration, information and advice regarding the various training schools and what they train for.

We shall print a list of approved educational institutions in the *Journal* from time to time, with the permission of Mr Nichols.

The Secretary complimented the committee on its efforts, and described the job done by it as bound to redound to the advantage of the veteran in the latter's search for education in the healing arts under the G I Bill of Rights.

The Secretary moved the acceptance of the report. This motion was seconded by a member, and it was so ordered by vote of the Committee.

Committee on Physical Therapy — Dr Arthur L Watkins, Middlesex South, chairman

The following report was offered by the chairman.

The purpose of this committee has been to acquaint and educate the general practitioner with the use of those physical therapeutic measures that are of value in medical practice. With this end in view an article, "Physical Medicine in Rehabilitation," was published in the February 15 issue of the *Journal*. During the past few years the interest of physicians specializing in physical therapy has been broadened to also include occupational therapy, and the name physical medicine has been generally used to indicate both physical and occupational therapy, and the use of physical agents in diagnosis and for the prevention of disease.

It is accordingly recommended that the activities of this committee be enlarged to include occupational therapy in its relation to medical practice and that the name of the committee be changed to the Committee on Physical Medicine.

Dr Leavitt moved the acceptance of the report and the adoption of the recommendations. This motion was seconded by Dr Gardner, and it was so ordered by vote of the Committee.

Committee on Rehabilitation — Dr Joseph H Shortell, Suffolk, chairman

In the absence of Dr Shortell, the Secretary said that it was expected that a report from this committee would be available for discussion at this meeting. He added that the report had not been received. For the information of the Committee, he said that the report, when received, would deal with a fee schedule that the Massachusetts Department of Rehabilitation sought to have set up in dealing with payments for medical services rendered to those of our people whose disabilities were static and remediable.

He said that if the individual were to profit under this program, actual indigence need not be shown. Such an individual, however, must show that he is unable through his own efforts to meet the costs of his rehabilitation. He added that a hernia that was impairing an individual's ability to follow a gainful occupation would be regarded, under this program, as a disability that was static and remediable.

Committee on Industrial Health — Dr Dwight O'Hara, Middlesex South, chairman

This report, which was offered by the chairman, is as follows:

During the past year, the Committee on Industrial Health has met as a whole four times, its subcommittees have met oftener. Among the subjects discussed at some length were rehabilitation in industry, aluminum therapy and prophylaxis for silicosis, various types of programs for postgraduate education, sarcoid-like reactions to chemical irritants and the merits of bills dealing with industrial health before the current sessions of the Legislature. With the approval of the Committee on Legislation we expressed ourselves in writing concerning these legislative matters to the proper state authorities. The committee co-operated with the War Participation Committee in emphasizing the responsibilities of doctors in the control of industrial absenteeism, and has continued to furnish editorial material which has been cordially accepted by the editor of the *Journal*. During the year, the committee has continued its discussions of industrial health in the small manufacturing plants of the Commonwealth. It has formulated its ideas on this subject to some extent, and would ordinarily embody them in this report. The fact that the annual report could not be presented to the Council as a whole, however, led us to publish this material in the April 5 issue of the *Journal* under the title "A Statement Concerning Industrial Hygiene in the Small Plants of Massachusetts." Your committee considers this statement to be its main contribution for the year.

The committee has from time to time aided industrial plants by making medical contacts for them, and has succeeded in placing a few physicians in industrial positions. Members of the committee have visited industrial plants in several parts of the Commonwealth on the invitation of their managements. The committee had planned for and hoped for larger participation in the program of the annual meeting of the Society, and had tentatively arranged for doctors to visit one of the large shipbuilding plants in Boston in connection with the meeting this year. A subcommittee was already in action in these matters when it became known that the meeting for 1945 was cancelled.

On May 8, under the auspices of the Hampden District Medical Society and the Springfield Academy of Medicine, the committee presented four speakers in an afternoon-and-evening program in Springfield. The papers were

arranged particularly to interest the general practitioner, and were well received, although they did not attempt to reproduce in volume the programs held in Boston in 1942 and 1943.

Dr O'Hara moved the acceptance of the report. This motion was seconded by Dr W H Allen, and it was so ordered by vote of the Committee.

Committee Appointed to Make Recommendations as to the Choice of Future Directors of the Blue Shield — Dr Leland S McKittrick, Suffolk, chairman

This report, which in the absence of the chairman was offered by the Secretary, is as follows:

The committee met at 8 Fenway on April 18, 1945. The committee was fully represented except for Dr Peirce H. Leavitt, who was out of the city and not available. In addition to the members of the committee, Dr Elmer S Bagnall and Dr Reginald Fitz were present.

It was voted to recommend to the Corporation the appointment of the following five men to replace those whose term of office ends this year:

Mr Oliver G Pratt — Reappointment
Mr Thomas G Brown — Reappointment
Dr Elmer S Bagnall — To replace Dr Mongan
Mr Ernest Johnson — Reappointment
Mr Daniel Boyle — Reappointment

The attendance record of the present Board of Directors was reviewed, and it was voted to recommend that Dr Frank R Ober, whose office expires in 1947, be asked to resign and that Dr Arthur W Allen, 266 Beacon Street, Boston, be elected to fill his place.

The President observed that he was not present when the above recommendations were made.

Dr Ober said that he had missed two or three meetings of the Board of Directors of the Blue Shield because the meetings were not always held as originally scheduled and that on those occasions he had made arrangements to be elsewhere when these meetings were finally held.

Dr Munro moved the acceptance of the report. This motion was seconded by Dr W H Allen.

Dr Bagnall explained that the Committee had been appointed because it seemed desirable to have a group of men who were sitting in continuity, and thinking at the time about the directorate in terms of the needs of the Blue Shield.

Dr Reardon asked if he had understood it correctly that Dr Mongan's name had been dropped from the list. The president replied in the affirmative.

Dr Reardon asked if Dr Mongan had been consulted and if there was any reason given for dropping him. The President replied he did not know, repeating that he was not present when the selections were made.

Dr Reardon said that it seemed to him that Dr Mongan is a man who deserves every consideration from the Society and from every fellow of the Society. He added:

He has been a tireless worker, giving time and energy and every effort for the benefit of the Society, and I should think it would be only a matter of courtesy to him to ask him if he did not want to serve any longer, if so, that would be the time to drop him.

I do not believe that a man who has given such service as he has given to the Society should be dropped without an adequate excuse

I am not a member of the Committee, and I am not speaking as a member of the Committee, but I do think that he is such a valuable man to the Society that he should be retained on the Board. Personally, I should like to see his name still go down on that list of names suggested

The President said he was not seeking any office, that he was a bit tired and that instead of desiring to take on a new job, he would like to be relieved of some he already had

Dr Fitz said that it was his recollection that Dr Mongan had finished his term. The President confirmed this

Dr O'Hara said that he shared everybody's feeling toward Dr Mongan but that this was a replacement at a perfectly natural time and that nobody should take umbrage at it

Dr Munro said that he was present at the meeting of the committee and that much time had been spent in canvassing the situation. He added that the committee had available for its use information that is not available to the Executive Committee, relative to plans, policies, financial conditions, financial commitments and out-of-state relations of the Blue Cross and Blue Shield, and that the deliberations were conducted in a spirit of friendliness to all, with the welfare of the Blue Shield the paramount issue

The report was accepted by vote of the Committee

Committee on Postwar Loan Fund—Dr George Leonard Schadt, Hampden, chairman

The report, which is as follows, was offered by the chairman

The Committee on Postwar Loan Fund, at a meeting held on May 2, 1945, decided that the time has now arrived to set up a postwar loan fund. It therefore recommends that

- (1) A sum of not more than \$25,000 of the Society's funds be drawn on for this purpose
- (2) That the President be empowered to appoint a committee of five, to include the treasurer and secretary of the Society and the present chairman of the Committee on Postwar Loan Fund, to administer this fund in accordance with the recommendations made by this committee in the report presented on May 22, 1944 as follows
- (3) That the amount of loan granted be left to the discretion of the board or committee appointed by the President
- (4) That just enough interest be charged—not to exceed 2 per cent—to cover carrying charges and remind the member obtaining a loan of his obligation
- (5) That no endorsers be required
- (6) That loans shall be limited to a period of twelve months subject to renewal at the discretion of the board or committee appointed
- (7) That only those who were members, in good standing of the Massachusetts Medical Society on the date they entered the armed forces shall be permitted to borrow from this fund

(8) That, to inform members of the Society in the armed forces of the availability of this fund, information be printed in the *New England Journal of Medicine*. There shall also appear in a box on the cover of the *Journal* an announcement calling attention of the members to the article on the inside page

(9) That form letters shall be sent to the members in the armed forces notifying them of the existence of this fund

(10) That form letters shall be sent out to the other members of the Society with the annual bills for dues bringing to their attention the existence of this fund and its purpose

(11) That the fund shall be administered from the headquarters of the Massachusetts Medical Society

Dr Schadt announced that the recommendations contained in the report had the approval of the Committee on Finance

He moved the acceptance of the report. This motion was seconded by Dr Leavitt, and it was so ordered by vote of the Committee

Dr Schadt moved the adoption of the first recommendation. This motion was seconded by Dr Chapin. With regard to the personnel setup under the recommendation, Dr Schadt said that he was in agreement with those who criticized this on the basis that it usurped the President's prerogative. He added that he had no particular desire to serve on the committee, but that he would do so if he were appointed. The recommendation was adopted by vote of the Committee

Recommendations 2, 3, 4, and 5 were adopted by vote of the Committee without debate. Dr Schadt moved the adoption of the sixth recommendation. This motion was seconded by Dr Leavitt. After considerable debate, which had principally to do with the question of enlarging the numbers who might be permitted to participate in the plan, it was voted by the Committee to adopt the recommendation as originally offered. Recommendations 7, 8, 9, 10, and 11 were severally moved by Dr Schadt for adoption. These motions were seconded, and they were so ordered by vote of the Committee

NEW BUSINESS

The Secretary was in the receipt of the following communication

Dr Michael A Tighe, Secretary
Massachusetts Medical Society
Boston, Massachusetts

Dear Dr Tighe

On February 16 Dr Bagnall submitted to me a letter which he had received from W. L. Bell & Co., an insurance management corporation. The substance of this letter was a request that the Massachusetts Medical Society approve an accident and health cash indemnity policy of the National Casualty Company of Detroit, Michigan. Mr. Bell stated in his letter that this was a group type of policy in which his corporation was endeavoring to interest such societies as the Massachusetts Medical Society and its county divisions as well as local medical societies, and such organizations as the Massachusetts Bar Association. This plan if subscribed to in groups, would allow the premium to be at a comparatively low rate.

Dr Bagnall, in submitting it to me, suggested that I review the proposition and judge as to its merits for the Massachusetts Medical Society.

In the furtherance of Dr Bagnall's request I did review the data submitted and also had Mr Bell submit the names of any organizations in the Commonwealth who are interested in this proposition. Also, there was submitted a sample copy of the insurance contract.

After careful review of the entire matter I feel that there is certain merit to this type of group cash indemnity policy and that possibly certain members of our organization might wish to avail themselves of the reduced premium payments which would be available. It is my understanding that such a plan as submitted by Mr Bell would require fifty per cent of our membership participating before such premium reduction would be available.

Any plan for the insurance of our membership necessarily merits careful study and analysis, both pro and con. Such a plan also needs careful consideration, not only of the financial stability of the parent company but also of their local representatives. The results that have been obtained where the plan is already in existence need study in order to evaluate the proposition. Therefore, I recommend that the Executive Committee of the Council of the Massachusetts Medical Society allow the matter to be presented to them for consideration, and if deemed advisable, that a committee of three be appointed by the president of the Massachusetts Medical Society to study the matter and bring specific recommendation to the attention of the Executive Committee at a future meeting.

I submit a resolution in order to bring this formally before the Executive Committee.

Yours very sincerely,

(Signed) CHARLES J KICKHAM

Dr Kickham moved that the president appoint a committee of five to study the plan for a group accident and health insurance policy. This motion was seconded by Dr Leavitt.

Dr Kickham said that his investigations showed that eleven of the eighteen districts were now covered by one insurance company. He added that the Norfolk District had had this matter under investigation for some time and that there seemed to be a demand in that district for this type of insurance.

Dr Phippen said that inasmuch as eleven of the district societies had already entered this field on their own, and were satisfied, it might be well to leave the matter of what the other districts would do in their own hands. Dr Reardon and Dr W F Ryan, Middlesex North, expressed a like view.

Dr Kickham's motion was defeated by vote of the Committee.

At that point, the President read a telegram from Chicago that announced that on the next day, Senator Robert F Wagner, of New York, would submit a revised Wagner Bill.

Dr Dwight O'Hara, Middlesex South, introduced the following amendment to the by-laws:

The by-laws of the Massachusetts Medical Society are hereby amended by adding a new chapter, to be known as Chapter X. This chapter shall read as follows: Any provision or provisions of these by-laws may be temporarily waived, provided such waiver is not in conflict with the laws of the Commonwealth, provided the provision or provisions sought to be waived be clearly designated,

provided the period during which such waived provision or provisions are to continue be definitely stated, provided notice of the proposed waiver accompany the call of the annual meeting and provided the members present at such an annual meeting unanimously consent.

Dr O'Hara moved the approval of the amendment. This motion was seconded by Dr Leavitt.

Dr O'Hara explained that as the by-laws now stand none of its provisions could be waived and that circumstances might arise in the future that might make such an act desirable.

Dr O'Hara's motion to approve the amendment was so ordered by vote of the Committee (The amendment will go to the annual meeting of the Society in 1946 for rejection or adoption).

The President read the following obituaries:

Dr John C V Fisher, of West Roxbury, died February 20. He was in his fifty-third year.

He received his degree from Boston University School of Medicine in 1917. He served as a surgeon for the United States Merchant Marine during the first world war. He had practiced in Boston since 1919 and had been obstetrician at the Massachusetts Memorial Hospitals since 1928. He was associate professor of obstetrics at Boston University School of Medicine. He was a fellow of the American College of Surgeons, and a member of the New England Obstetrical and Gynecological Society.

Dr Fisher was president of the Norfolk District Medical Society from 1943 to 1944 and had been a member of the Council of the Massachusetts Medical Society for several years.

His widow and a brother survive.

Dr Edwin R Leib, of Worcester, died May 3. He was in his seventy-first year.

He received his degree from Boston University School of Medicine in 1899. He retired as chief of the medical service at Hahnemann Hospital a few months ago but remained on the staff as a consultant. He was also a consultant on the Belmont Hospital staff. Dr Leib had served as epidemiologist in the Worcester Health Department for more than thirty years. He was president of the Worcester Blood Bank.

His memberships included the Worcester District Medical Society of which he was a past president, as well as a councilor at the time of his death. He was a fellow of the American Medical Association.

His widow and a brother survive.

At the direction of the President, the Committee stood for one minute in silent tribute to the memory of these deceased councilors.

The Secretary submitted the following changes in membership:

Membership as of May 23, 1944

<i>Losses</i>	
Deaths	100
Resignations	11
Deprivations	16
Total	127

<i>Gains</i>	
New fellows	119
Reinstatements	11
Total	130
<i>Net Gain</i>	3

Membership as of May 23, 1945

5783

5786

The President submitted the following list of ad interim appointments

To the Council Dr Louis A Sieracki, Norfolk, to replace Dr J C V Fisher, deceased Dr Philip E Meltzer, Suffolk, to replace Dr George B Fenwick, deceased

To the Section of Anesthesiology Dr Sidney C Wiggin, chairman, and Dr Leo V Hand, secretary

To the Committee on Legislation Dr Curtus C Tripp, representing Bristol South, to take the place of Dr Edwin D Gardner, resigned

To the Committee on Public Relations Dr Milton J Quinn, representing Middlesex East, to take the place of Dr J Harper Blaisdell, deceased

To the Subcommittee on Public Information of the Committee on Public Relations Drs John Fallon, chairman, Michael A Tighe, Richard M Smith, Ralph R Stratton, Roy J Ward, Roger T Doyle, Roy J Heffernan and Howard F Root

To the Subcommittee on Labor and Industry of the Committee on Public Relations Dr Daniel B Reardon, chairman, George J Connor, Daniel J Ellison, John Fallon and Michael A. Tighe

To the Subcommittee on Hospitals of the Committee on Postwar Planning Dr Clifton T Perkins

To the Subcommittee on Organization of the Committee on Postwar Planning Dr Charles E Mongan

To the Subcommittee on Postgraduate Education of the Committee on Postwar Planning Drs Harry C Solomon and Charles G Mixer

To the Committee to Make Recommendations as to the Choice of Future Directors of the Blue Shield Drs Leland S McKittrick, chairman (term expires May, 1949), George G Smith (term expires May, 1948), Elliott P Joslin (term expires May, 1947), Donald Munro (term expires May, 1946) and Peirce H Leavitt (term expires May, 1945)

These appointments were confirmed by vote of the Committee

At that point the President introduced Dr Reginald Fitz, president of the Massachusetts Medical Society for the year 1945-1946. He was greeted with loud applause

Dr Fitz submitted a list of nominations to standing committees. He moved the approval of these nominations. This motion was seconded by Dr Munro, and it was so ordered by vote of the Committee. Dr Fitz then read a list of nominations to special committees and subcommittees. He moved the approval of the nominations. This motion was seconded by Dr O'Hara, and it was so ordered by vote of the Committee. (The members of the standing and special committees for the year 1945-1946 appear elsewhere in this report.)

The President read the following communication from Dr John F Kenney, president of the Rhode Island Medical Society

Dr E S Bagnall, *President*
Massachusetts Medical Society
Groveland, Massachusetts

Dear Dr Bagnall

At the meeting of the House of Delegates of the Rhode Island Medical Society held on May 9, the House voted unanimously that the Rhode Island Medical Society should take leadership at the present time in forming a New England Medical Council of the medical societies for the purpose of discussing mutual problems

A year ago it was proposed by the Rhode Island Medical Society that such a council be activated and an attempt was made to interest the other New England societies. We now hope that this plan may be realized and we are confident that it would be most advantageous to all of us in finding ways in which to solve both local and national problems that directly concern the practice of medicine and the provision of medical and health services to the peoples in our states

I enclose a copy of the proposal as tentatively advanced last year to give you an idea of how such a council might possibly be organized and made workable

We shall appreciate your kindness in bringing this matter before your policy-making body, and I shall hope to hear from you in the near future relative to the decision of your society

When we have heard from you we shall be in a better position to set a definite date when a conference might be held here in Providence to formulate details

(Signed) JOHN F KENNEY, M D

May 19, 1945

The proposal referred to in the letter appears as Appendix No 9

Dr Leavitt moved that the Society participate in the plan proposed by Dr Kenney. This motion was seconded by Dr Munro, and it was so ordered by vote of the Committee

Dr Leavitt addressed the chair and said that he wished to express his approval of the way in which Dr Bagnall had run things during the year. "You have been fair," he added, "in a trying job, and I want personally to thank you for a job wonderfully well done"

There being no further business before the meeting at 5 20 p m, the President declared the meeting adjourned

MICHAEL A TIGHE, *Secretary*

APPENDIX NO 1

TREASURER'S REPORT

During 1944 income from dues was further reduced owing to more members being in the service with dues remitted — \$39,723 in 1944 as compared with \$43,390 in 1943. Non-resident dues dropped from \$1651 to \$1492 during the same period

Income from investments in the General Fund rose from \$3466 in 1943 to \$3969 in 1944, and from investments in the Building Fund from \$1776 in 1943 to \$1960 in 1944. An outstanding achievement was the increased income from the annual meeting contributed by the Committee on Arrangements and in large part due to the efforts of the Executive Secretary, \$3495 in 1944 as against \$1750 in 1943

The yield from securities held in the General Fund increased during the year from 2.40 to 2.43 per cent, and from those held in the Building Fund from 2.95 to 3.14 per cent.

Total value of the securities in the General Fund stands at \$167,614 book value and \$170,885 market value, an increase during the year of \$7056 and \$9838 respectively. Correspondingly in the Building Fund book value of holdings stands at \$68,170 and market value at \$70,858, an increase of \$5721 and \$5284 respectively

Changes in the portfolios of the two funds have largely been replacements of bonds matured or called by bonds of similar character, government issues and a slight increase in preferred stocks

Ten thousand dollars (\$10,000) in Commonwealth of Massachusetts 3½ per cent bonds held in the Phillips Fund matured and were replaced by an equal amount in United States War Savings Series G bonds. Including these, the Society has increased its government bond holdings by \$22,000, this year, to a total of \$96,000

According to the vote of the Council in June, 1929, providing that interest received from the Building Fund principal could be applied toward the expenses of maintenance of society headquarters, this action has been followed and such income has not been added to the Building Fund total.

One thousand, one hundred and sixty-four dollars (\$1164) received for subscriptions to the *New England Journal of Medicine* from members in active service has been made over to the *Journal*, last year the comparative figure was \$750.

In 1944 total revenues to the Society amounted to \$52,903, an increase of \$935 over the previous year. Total expenses of the Society amounted to \$38,544, an increase of \$5411 over 1943. Excess of revenues over expenses was, therefore, \$14,359 for 1944.

The Society ends 1944 with total assets of cash and securities of \$272,451, an increase during the year of \$22,066.

A cordial and instructive relation has been maintained with the investment counselors. I should like to reiterate how congenial and helpful has been the aid given this office by the clerical staff of the *New England Journal of Medicine*, and to emphasize the advantage of the present close proximity of the offices for mutual speedy handling of various problems that arise.

A breakdown of comparative expenses for 1943 and 1944 is appended.

EXPENSES	1943	1944
Salaries		
Secretary	\$3000 00	\$3000 00
Executive Secretary	3000 00	3000 00
Treasurer	2000 00	2000 00
Expenses		
President	693 80	714 36
Secretary	1925 84	2195 00
Treasurer	1719 43	2113 04
Delegates to A. M. A.	689 04	779 40
Maintenance of Society Headquarters (including clerical and other expenses)	4801 56	6538 64
Shattuck Lecture	200 00	200 00
Cotting Luncheons	302 00	358 50
Committees		
Ethics and Discipline	110 71	159 07
Executive	230 21	543 47

APPENDIX NO 2

REPORT OF THE COMMITTEE ON MEMBERSHIP

The Committee on Membership, meeting with the supervising censors, as provided in Chapter V, Section 1, of the by-laws, recommends

That the following-named fellows applying for retirement and with all dues paid and in good standing, be allowed to retire under the provisions of the by-laws, Chapter I, Section 5

Balch, Franklin G (Norfolk), 109 Moss Hill Road, Jamaica Plain

Dewis, John W (Essex South), 7 Gregory Street, Marblehead (Journal requested)

Dunn, William A (Suffolk), 39 Somerset Street, Boston.

Harriman, Perley (Essex South), 11 Atlantic Street, Lynn (Journal requested)

Howell, William W (Norfolk), 44 Eliot Street, Jamaica Plain

Leland, Forrest L (Hampden), 6 Gaylord Street, South Hadley Falls

MacCorison, Carl C (nonresident), North Berwick, Maine.

MacLennan, Angus D (Suffolk), 411 Marlboro Street, Boston

Moore, Fredrika (Middlesex South), 983 Memorial Drive, Cambridge

Newhall, Harvey F (Essex South), 51 Nahant Street, Lynn

Royal, Herbert B (Worcester), Still River Road, Harvard (Journal requested)

Smith, Hervey L (Hampden), 235 Queens Lane, Palm Beach, Florida

Sullivan, Cornelius A (Norfolk South), 20 Pond Street, South Braintree (Journal requested)

Sullivan, Joseph L (Norfolk), 89 Waverley Street, Roxbury

That the following-named fellows applying for resignation and with all dues paid and in good standing, be allowed to resign under the provisions of the by-laws, Chapter I, Section 7, such resignation effective January 1, 1945

Kirkpatrick, Milton E (nonresident), 1737 Prytania Street, New Orleans, Louisiana

McKhann, Charles F (nonresident), P O Box 118, R P Annex, Detroit 32, Michigan

That the following-named fellow applying for resignation be allowed to resign, with remission of dues owed the Society, under the provisions of the by-laws, Chapter I, Sections 6 and 7 of the by-laws, such resignation effective January 1, 1945

Clarke, Samuel T (nonresident), 240 West First Street, Reno, Nevada

That the following-named fellows, who are ill and incapacitated, shall have the dues owed the Society remitted under the provisions of the by-laws, Chapter I, Section 6

Harkins, William J (Norfolk South), 20 Whitney Street, Quincy 1945

Krieger, William L (Norfolk South), 15 Lincoln Avenue, Wollaston 1945

Shukle, R M (Suffolk), 432 Marlboro Street, Boston 1944 and 1945

That the following-named fellow, who had resigned from the Society while in good standing, be reinstated under the provisions of the by-laws, Chapter I, Section 10

Wilens, Gustav (Middlesex South), Cochituate Road, Wayland

That the following-named fellows, who have been deprived of membership for the nonpayment of dues, be reinstated as fellows of the Society, provided their arrears in dues at the time of deprivation, plus their dues for the year 1945 be sent to the treasurer of the Society, in accordance with the by-laws, Chapter I, Section 10

Aschillo, H V (Hampshire), 16 Centre Street, Northampton

Butler, Harry H (Norfolk), 48 Winchester Street, Brookline

Rosen, Edward (Suffolk), 164 Shirley Avenue, Revere

That the following-named fellows be allowed to change their membership from one district society to another, with out change of legal residence, under the provisions of the by-laws, Chapter III, Section 3

Anderson, Donald G, 46 Orchard Street, Jamaica Plain (Remain in Suffolk)

Anderson, Erna G, 46 Orchard Street, Jamaica Plain (Remain in Suffolk)

Goodman, Joseph, Clay Brook Road, Dover (Remain in Middlesex South)

Hvde, Harold V, 987 Memorial Drive, Cambridge
(Remain in Suffolk)
Joice, Charles C, 31 Conant Street, Danvers
(Essex South to Plymouth)
McMackin, Francis L, 230 Brattle Street, Cambridge
(Norfolk to Suffolk.)
Robins, Samuel A, 15 Galvin Road, Newton Centre
(Middlesex South to Norfolk.)
Todd, John J, 23 Windmere Road, Milton
(Remain in Suffolk.)

APPENDIX NO 3

REPORT OF THE COMMITTEE ON PUBLIC RELATIONS

There have been two meetings of the Committee on Public Relations. A summary of the report of the first meeting has been sent you.

The second meeting was held on April 25, 1945, and unfortunately your secretary was unable to be there. There were present, in addition to President Bagnall and Secretary Tighe, representatives from nine districts. The first subject studied was a report of the Subcommittee on Public Information, which was received and approved. This report is to be given by the chairman of the Subcommittee, Dr John Fallon. The second question studied was a report of the Subcommittee on Tax-Supported Medical Care, which will be given later by Dr Dumphy. This report was discussed at some length and approved with two members dissenting.

The summary of the report of the first meeting is as follows:

The members of this committee listened with great interest to a recital of the activities of the Committee on Postwar Planning by Dr Howard F Root, its chairman. It expressed a desire to support these activities in every way possible.

The Subcommittee on Labor and Industry presented an interesting report on its activities to date. It was the belief of the Committee on Public Relations that the subcommittee should pursue its activities. A report of progress will be presented by this subcommittee later in this meeting.

The Subcommittee on Tax-Supported Medical Care reported on certain conversations that it had in March with Mr Long, Commissioner of Veterans Aid and Pensions, anent payments for the medical treatment of needy veterans. This subcommittee signified that it intended to consult with the Massachusetts Commissioner of Welfare along the same lines. The Committee on Public Relations approves the report and the recommendations contained therein. The Committee on Public Relations recommended that the Subcommittee on Tax-Supported Medical Care reconsider the question of charges to recipients of welfare assistance and old-age assistance with a view that payment be made for all medical and surgical services rendered.

After considerable discussion with Dr Vlado A Getting, Commissioner of Public Health, and Dr Geoffrey Edsall, of that department, the Committee on Public Relations approved, in principle, the plan of the Department of Public Health for the collection of blood, voluntarily donated, and the distribution of the fractions of the blood to the citizens of Massachusetts without charge. Such distribution is to be made on the recommendation of physicians.

ALBERT A HORNOR, *Secretary*

APPENDIX NO 4

REPORT OF THE COMMITTEE ON LABOR AND INDUSTRY

The Subcommittee on Labor and Industry of the Committee on Public Relations offers this report as one of information only.

The subcommittee had separate conferences with representatives of the two major labor groups in Massachusetts — the CIO and the A F of L. These conferences were held for the purpose of obtaining first-hand knowledge of the feeling of labor with regard to medical care and how it is to be paid for.

It was found that both these groups have definite ideas as to their demands in this matter. The CIO defines these demands in terms of the following language: "Adequate medical care at the price the worker is able to pay." The A F of L says its demands can be met by an insurance scheme, the entire cost of which is to be borne by industry. The subcommittee has reason to believe that this very same view is held by the CIO although this fact did not come out in our conference with its representatives.

The representatives of both organizations disclaimed any desire to see the Government in this field, provided their demands could be met in any other way, because in a government scheme labor would undoubtedly be compelled to contribute its share of the costs.

The subcommittee learned that, in lieu of wage increases which could not be granted because of the Little Steel Formula, many industries had contracted with private insurance carriers to cover the medical-care costs or part of these costs incurred by their employees when ill.

The subcommittee also learned that the Massachusetts office of the National Labor Relations Board frequently took a hand in the negotiations leading to this end. This latter information has been passed on to the Blue Shield and Blue Cross as suitable fields to explore. We are informed that these conferences have already resulted in an increased enrollment by CIO members in the Blue Shield.

The subcommittee finds from another source how widespread has become the practice of providing for the medical-care costs of those employed in industry through private carriers. Reference here is to the report of the Advisory Council of the Massachusetts Unemployment Commission which says that, of the 780,000 people in Massachusetts employed in industry, over 60 per cent have, through private carriers, provided for their medical-care costs in whole or in part.

Supplementing the meetings that the committee had with representatives of the CIO and the A F of L, a meeting was held with a committee of the Associated Industries of Massachusetts on May 9, 1945, at the Hotel Kenmore. Those present were Mr Lawrence Muench, president of Hood Rubber Company, Watertown, Mr Philip M Morgan, president of the Morgan Construction Company, Worcester, Mr Horace C Houghton, personnel director of the Bethlehem Quincy Yard and assistant to the general manager, Mr George E Williamson, vice-president and treasurer of the Strathmore Paper Company, Springfield, Mr Roy F Williams, executive vice-president of the Associated Industries, and Mr Jarvis Hunt, attorney for the Associated Industries.

The general subject of medical-care costs was informally discussed, a subject in which these representatives of industry were vitally interested. In their opinion there were two phases of this problem — one relating to medical care and its costs and the other to the income of the employee during his illness. After considerable discussion it was their opinion that the cost of medical care could not be borne by industry at the present time. The reason given for this opinion was that, if borne by industry, it would be an additional cost to production thereby rendering their cost higher than that of their competitors in neighboring states, who did not have the same coverage. They felt that the payment of benefits to employees was a social and economic problem and should probably be covered by state or national legislation. Each of these representatives of industry cited systems in practice at their places of business with reference to accident insurance. In all cases, the cost of this insurance was paid for by the employee by weekly deductions from his salary, but the operating expenses, such as rooms, clerical help and investment of funds, were borne by the employer. A general dis-

cussion was entered into with reference to the Vaughn Bill now before the Legislature, which contains liberal accident and health benefits and would presumably be administered by a board, such as the Industrial Accident Board. It was generally agreed by those present that such legislation was a step toward state medicine, which, in the end, might lead to national medical supervision. Therefore, at the present time, they were not in favor of such legislation. It was an interesting two-hour discussion.

DANIEL B. REARDON, *Chairman*
 GEORGE J. CONNOR
 DANIEL J. ELLISON
 JOHN FALLON
 MICHAEL A. TIGHE

APPENDIX NO 5

PROPOSED RULES OF THE MASSACHUSETTS DEPARTMENT OF PUBLIC WELFARE FOR REIMBURSEMENT FOR PHYSICIANS' SERVICES IN HOSPITALS IN WHICH THE STAFF DOES NOT GIVE FREE CARE TO WARD PATIENTS

The department will participate in grants to recipients of public assistance for physicians' services in hospitals in which the staff does not give free care. This policy applies only to those hospitals that are approximately fifteen miles or more distant from any hospital in which free care by the staff may be obtained. A tentative list of these hospitals is as follows:

Plunkett Memorial Hospital	Adams
Farren Memorial Hospital	Montague
Franklin County Public Hospital	Greenfield
Fairview Hospital	Great Barrington
North Adams Hospital	North Adams
Wing Memorial Hospital	Palmer
Mary Lane Hospital	Ware
Community Memorial Hospital	Ayer
Webster District Hospital	Webster
Emerson Hospital	Concord
St. Luke's Hospital	Middleboro
Norwood Hospital	Norwood
Jordan Hospital	Plymouth
Cape Cod Hospital	Hyannis
Tobey Hospital	Wareham
Nantucket Cottage Hospital	Nantucket
Martha's Vineyard Hospital	Oak Bluffs

In some instances, the staff gives free care to ward patients from the community in which the hospital is located, and it is expected that this policy will continue. Exception to this list of hospitals will be made in the event of an emergency in which the nearest available hospital may be used and department participation will be granted.

Surgical Fees. These will be paid at a rate not to exceed the fees as listed by the Massachusetts Medical Service (Blue Shield) at the present time for each operation or procedure. All fees include preoperative and postoperative care. When two or more operations are performed for the same medical cause within two months, total surgical fees shall not exceed \$150.00. Care needed beyond this time will be reimbursed according to the schedule of medical fees. Fees for assistant surgeons, when necessary, will be included in the total surgical fees on a basis of approximately 10 per cent of the total fee.

Anesthesia. When there is no resident anesthetist in the hospital, fees for anesthesia will be allowed at a rate not to exceed the fees for anesthesia as listed by the Massachusetts Medical Service and only to a licensed physician other than the surgeon or assistant surgeon.

Medical Fees. Fee schedules for medical cases will be based on a minimum number of visits necessary for the patient. Participation by the department will not exceed the state's proportionate share of a \$4.00 fee for the first day and \$2.00 for each visit thereafter. Total reimbursement for physicians' fees during any one hospital stay for the first two months shall not exceed \$150.00. For a stay of more than two months, physicians' fees will be reimbursed at the rate of \$2.00 a visit, after the case has been discussed by the physician with the local board of public welfare.

APPENDIX NO 6

REPORT OF THE COMMITTEE ON LEGISLATION

This report may appear to the members of the Executive Committee unreasonably brief having in mind the many bills affecting one way or another the health of our citizens in which the members of the Society are naturally so much interested. To tabulate the various bills that have been heard, and to set forth the outcome of hearings on these bills without at least briefly discussing the subject matter of them would not greatly aid the members of the Executive Committee in their deliberation on these important matters of legislation.

Although there have been a great many bills that have been considered at the present time only a few have come out of committees, but one has been passed by the Senate and has been signed by the Governor. This is a bill that permits limited licensure not only to interns in hospitals but also interns and fellows in clinics, both incorporated and nonincorporated. As is the case in a great many of these bills, so in this one there were certain things that were good and certain things that we thought should not be approved. We stated our reasons for changes that we thought should have been made in the bill, but they were not made. This bill is now law.

After an all-day hearing before the Committee on Public Health, and after discussion in executive session by that committee, the bill giving chiropractors a separate board of registration was reported favorably. That bill is now in the hands of the Committee on Ways and Means and without doubt will come up for consideration in the House and perhaps in the Senate.

Your committee favored, with a single exception, House Bill 149, which permits children with rheumatic heart disease to receive treatment at the North Reading Sanatorium, that bill has been favorably reported and it, too, is now in the hands of the Committee on Ways and Means.

The annual vaccination bill was given leave to withdraw. There was considerable discussion on two bills having to do with changes in the Division of Occupational Hygiene. One of these bills would abolish the division, and that was given leave to withdraw in both House and Senate.

A bill requiring filing of annual returns by corporations conducting medical schools passed in the House and has been signed by the Governor.

The great majority of bills of interest to the members of the Society, however, are still under consideration and have not as yet been reported by the respective committees hearing these bills.

Four hearings were conducted by the Committee of Education having to do with osteopaths. There were originally three bills, so-called "osteopathic bills." One of these setting up a special board of examination in osteopathy was withdrawn. Briefly, one of the other two bills provided for the licensure in this state of a diplomate of the National Board of Osteopathic Examiners, and the second, in substance, provided that any graduate of any osteopathic school approved by the American Osteopathic Association would be permitted to take examination for registration by the Board of Registration in medicine. A good deal of groundwork was covered before we attempted to set forth our views in these matters. The Committee of Education at the State House rather felt that, if things were permitted to go along as they exist at the present time, within eight to ten years there would be no osteopaths practicing in the Commonwealth. Reliable sources indicate that 300,000 to 500,000 citizens in the Commonwealth want osteopathic physicians. In executive session the Committee of Education had interested parties appear before it and many phases of this problem were discussed.

A bill that has already had one hearing in the Senate, and which will be amended, may become law. That bill, in substance, would add two members to the present Approving Authority — one an osteopathic physician, and the second a lay person, both to be appointed by the Governor with the approval of the Council. It would further provide that a diplomate of the National Board of Osteopathic Examiners may present his or her certificate to the Board of Registration in Medicine, and at the discretion of the Board be permitted to practice medicine in this state, provided that such diplomate shall have graduated from an osteopathic school approved by the Approving Authority.

Seven full-day hearings before the Committee on Public Health were held for discussion of the group of bills that may be considered together as those affecting substandard schools. The purpose of these bills may be summarized without material inaccuracy as measures seeking to repeal the law as it now exists, or to change the law materially so as to permit graduates of any unapproved school the right to take the examination given by the Board of Registration in Medicine. These bills thus far have not been reported by the Committee on Public Health.

The members of the Committee on Legislation have worked untiringly in these matters entrusted to their care. The members of the committee are indeed grateful for the real help given us by some who voluntarily offered assistance, and from others from whom we asked help and received it. We are particularly grateful to the members of our profession engaged in general practice who have put themselves out to see to it that proper information aiding legislators in their deliberation on these matters was given to them. We know at the present time, however, that there are members of the Senate and the House who would have benefited in their thoughts on these various bills had they been given information to which they were and are entitled from members of the Massachusetts Medical Society. If reports that we have received are accurate, some of these legislators thus far have not been interviewed by any member of the Massachusetts Medical Society.

At this time it would seem to serve no useful purpose to comment on certain matters which will perhaps result in a most discouraging final outcome on the work which has been done thus far this year in matters of legislation. We ask the Executive Committee and the Council to hear us again in the matter of suggestions as to policies for the future. We have had almost daily assistance from our legal adviser, Mr. Charles J. Dunn, and for this we are indeed grateful.

This report is respectfully submitted, as heretofore stated, as a preliminary report, and on this report we ask your approval.

W E BROWNE, *Chairman*

APPENDIX NO 7

REPORT OF THE COMMITTEE ON POSTWAR PLANNING

The provision of necessary educational opportunities as well as opportunities for various types of professional activity desired by returning medical veterans is a first consideration in any plan for the postwar era. The most recent analysis of 21,000 questionnaires returned by physicians in the armed forces indicates that more than 12,000 hospital residencies or long courses of postgraduate training will be required during the two-year period of demobilization. It is possible that this figure may be too conservative, since no expression of the desires of a large percentage of doctors in the service has been obtained. Present facilities appear to provide for only half this number. Therefore, a large number of such special opportunities must be provided either by increasing the appointments in existing hospitals or by adding new hospitals. Hospitals not now provided with interns and residencies need to organize teaching services for the training of such men.

The returns from this questionnaire indicate how fully the recent graduate in medicine appreciates the inadequacy of his training particularly along clinical lines. It is not sufficient to dismiss this as one of the exigencies of the war. If the same high standards of medical care to which the American people have been accustomed is to be maintained, notice must be taken of the inadequacy in preparation which looms large in the doctor trained in wartime and every effort bent toward its relief. The committee believes that the hospitals of the Commonwealth can and should play a most important part in any program directed toward that end.

Economic aspects of postwar practice are emphasized (*JAMA*) 128 (38-41, 1945) by a further analysis of these questionnaires which shows a large percentage of the medical officers in the group studied are interested in future specialty practice. Indeed, the group represented about half again as many as originally were engaged in special fields. In answer to questions concerning voluntary redistribution to areas needing physicians the important point came

out that nearly 29 per cent, or 6091, would go to such areas if there were hospital facilities. About 85 per cent of the officers indicated they did not desire to remain in government service.

One fifth of all medical officers who returned the questionnaire indicated an interest in the field of industrial medicine. Four times as many men wanted part-time positions in industrial medicine as wanted full-time positions. An important point is that many of those who wish to engage in part-time industrial practice would also like to take special training. It is clear that soon many questions will be addressed to us by medical officers in anticipation of their discharge from the Army within six months or a year seeking information about possible residencies, special courses from three to six months or longer in special cases but also opportunity for part-time or full-time work in industrial medicine or even full-time salary position in state hospitals as well as opportunities for location in private practice.

Provision should be made therefore to set up a service bureau at the society headquarters that can give information by mail or in person regarding the wide variety of opportunities in this state. This service bureau might naturally include the present Bureau of Clinical Information and it would necessarily work in close co-operation with the medical schools, which would be glad to refer men to it for information. This bureau would also work closely with the central bureau of the American Medical Association at Chicago. The Bureau of Information of the American Medical Association has set about collecting and tabulating information on medical facilities and needs for some months. This bureau has sent summary sheets to every county by states in the United States. These summary sheets will provide information about the population, number of physicians in each county, the economic status of that county as indicated by the size of its cities, the retail purchases per year and so forth. When these sheets have been analyzed the data will be available to each state and county unit for use in such local service bureaus as proposed here. Already more than half the Massachusetts district societies have sent in their summary sheets. It appears likely that as the months pass and the end of the war approaches the need for extra personnel at such a bureau at 8 Fenway may become urgent.

This bureau, then, under a central co-ordinating committee might serve not merely during the postwar period but afterward as an integrating agency for postgraduate instruction of all kinds in hospitals, medical schools and elsewhere for the service not only of returning veterans but also of all doctors and medical agencies.

The establishment of a permanent veterans' medical and hospital service in the Veterans Administration is proposed in a bill in the House of Representatives by Mrs. Rogers of Massachusetts and in a second bill by Mr. Priest of Tennessee. These two bills will be the subject of a report by a special committee of the Committee on Postwar Medical Service.

The physical fitness program will become increasingly important in the future, and leadership by the medical profession should not be withheld. The placing of four million Americans in Class 4F by Selective Service is the reason for anticipating a program for future aims at early correction and prevention of disqualifying defects.

Mr. Joseph Lawrence, director of the Washington office of the Council on Medical Service and Public Relations of the American Medical Association, recommends to all interested physicians the two pamphlets (Parts 5 and 6) covering the hearings of the Pepper Committee, officially entitled "The Subcommittee of the Committee on Education and Labor, United States Senate, Wartime Health and Education."

Postgraduate education must be provided in medical schools and in hospitals, but also in communities at a considerable distance from medical schools. Education must become a prime function of the medical society and of the hospital, and its importance to the medical care of the American people must be understood in the future by trustees, laymen, editors, representatives of labor and allied organizations. Thus, a major objective must be the securing of better co-operative teamwork between physicians, dentists, nurses and public-health agencies, both public and private.

Modern medical methods of diagnosis and therapeutics require more skill, more education, more time, more equipment and more intelligent co-operation by patient and doctor than ever before. To attain a better quality with wider

distribution of medical care and lower costs must be an objective of us all. Prepayment sickness insurance plans need further study and trial.

It was obvious to the committee that its work must be carried out through subcommittees. Reports so far received from subcommittees may be briefly summarized.

Subcommittee on Hospitals, Dr Nathaniel Faxon, chairman. Although there are more than 200 hospitals in Massachusetts, of which 125 belong to the American Hospital Association, a recent analysis showed that only 35 hospitals were approved for offering residencies. More hospitals in Massachusetts and New England should organize staff members for teaching interns and residents. It is not essential that the hospital be large. Doctors genuinely interested in teaching can convey to an intern excellent teaching in a 35-bed hospital. Yet larger hospitals afford a more varied experience. Already first steps have been taken in the preparation of a statement intended for use by hospitals that desire to organize their staffs and resident services in order that they may classify as teaching hospitals. The details of this program, easily understood by physicians, are not so clear or so necessary in the minds of lay people. Joint meetings of staff and lay people in each community for improving and extending the educational service of hospitals not only to the interns but to the hospital staff and to patients as well are needed.

The Advisory Committee appointed by Governor Tobin will conduct a survey both of Massachusetts hospitals and nursing homes, which should provide entirely new data regarding medical care and medical needs in the Commonwealth.

Subcommittee on Medical Schools, Dr Charles F Branch, chairman. The medical schools of today are keenly interested in extending their service to the community. Their faculties possess special knowledge in the basic sciences which can be brought to medical groups at a distance by better organization of teaching through the Society's efforts.

Subcommittee on Postgraduate Education, Dr Richard Ohler, chairman. In an era of rapid scientific discovery varied and continuous programs of postgraduate instruction are necessary. No doctor five years out of medical school or more can practice successfully with the education acquired in his undergraduate years. Effort is being made to develop a varied program making use of hospitals and centers of education remote from metropolitan areas as well as in university centers and utilizing the co-operation of the Department of Public Health and Department of Education. The committee plans a limited number of teaching centers, each to act as a focus for a district circuit. The program should begin in the fall of 1945, and a detailed report will follow later.

Our present aim is to bring about a better understanding among physicians, hospital trustees and public-health agencies of the present unique opportunities presented to American medicine. Never before has the interest of the lay public in hospitals, doctors and medicine been so great. It has been stimulated by the war, and particularly by active participation as volunteers in hospitals and public-health organizations of men and women never before in immediate contact with such work. The public interest has been most clearly presented in the report presented before Senator Pepper's Subcommittee on Wartime Health and Education, whose hearings began last July and are still in progress. A series of meetings should be carried out in hospitals throughout the Commonwealth where physicians of hospital staffs, together with hospital trustees, editors and representatives of labor, may discuss under a panel form of program various proposals for providing hospital internships and residencies and extending medical care in the immediate community as well as in the Commonwealth. Speakers may be secured through this committee.

It is recommended that committees on postwar plans in each district society study the possibility of increasing the hospital residencies to be available for veteran physicians.

A meeting will be held Wednesday, June 20, at 5:00 p.m., at the Hotel Puritan of representatives of hospitals who wish to discuss plans for new internships and residencies. The provisions of the G. I. Bill of Rights become applicable to hospitals or other institutions offering educational opportunities when their residencies or other courses have been approved by the Board of Collegiate Authority, 200 Newbury Street, Boston. Hospitals are invited to be repre-

sented by the superintendent, trustees and a member of the medical attending staff.

HOWARD F. ROOT, Chairman
LEROY E. PARKINS, Secretary

APPENDIX NO 8

REPORT OF THE COMMITTEE ON ETHICS AND DISCIPLINE

The Committee on Ethics and Discipline is happy to report to the Executive Committee of the Council of the Massachusetts Medical Society that the ethical health of the Society is excellent. Only twenty complaints have been received to date for the year 1944-1945. However, each of these complaints, no matter how trivial, required investigation, hearings and discussion. The majority of the complaints were from laymen accusing fellows of unethical practice.

Two of these complaints were brought as a prelude to court procedure — the cases already slated for trial. These the committee refused to consider until judicial decision had been handed down.

The remaining cases of this group were thoroughly investigated, hearings given to both complainant and the accused fellow. In each case there was found to be either animosity or hope of financial gain on the part of the complainant, and the fellow was an innocent sufferer.

Two cases were referred to the committee from the State Board of Registration in Medicine concerning alleged unethical action on the part of two fellows — one of improper testimony in a trial, the other of falsifying records. The first fellow, after investigation, was judged to be innocent of unethical deportment, although his lack of judgment was evident. The second fellow was found guilty of falsifying his records and of giving false testimony on interrogation as to his actions. He was referred to the President for severe admonition.

Two cases concerned accusation of violation of the Code of Ethics by fellow against fellow.

The first case was dismissed because of the lack of real evidence of wrongdoing. In the second case, the defendant was found guilty of unethical conduct in advising with and the treatment of a patient still under the care of the complainant. The offending fellow was requested by the committee to send a written apology to the injured fellow. This was sent, accepted, a copy sent to the committee and the incident declared closed.

On April 11, 1945, the committee dealt with a case in which a fellow of the Society was charged with a serious violation of the Code of Ethics. He was found guilty and severely reprimanded by the President at the request of the committee.

ALLEN G. RICE
FRED R. JOUETT
ARCHIBALD R. GARDNER
RALPH R. STRATTON, Chairman

APPENDIX NO 9

PROPOSAL BY THE RHODE ISLAND MEDICAL SOCIETY FOR A COUNCIL OF THE MEDICAL SOCIETIES OF NEW ENGLAND

PREAMBLE

The main purpose of such a council would be to bring about closer co-operation between the medical societies of the New England states in the development of plans relative to organized medicine, and plans for the furtherance of all phases of public health under medical supervision.

Recognizing that each society has problems peculiarly its own that cannot be solved by any general provision, the council might serve as a body to deliberate on those larger matters in which each of the societies is equally concerned. Also, in view of the fact that each society is a component unit of the American Medical Association, this council should

now the principle that it shall not seek to supersede the control now exercised on organized medicine by the House of Delegates of the national organization

ORGANIZATION

The council might be composed of the presidents or secretaries of the constituent state societies, and of two additional representatives, who shall be appointed by the president or the governing body of the respective state society as it may determine, each to serve for stated terms

Officers of the council might be elected by the council itself, to serve for one year, or until their successors were duly qualified and elected

Meetings might be held at stated times during the year, and alternately in the various states, and also might be held at such other times as deemed necessary by the president of the council

The council might make such rules and regulations as it deemed advisable and necessary for its successful operation

The expenses of the council organization might be prorated annually among the six state medical societies

METHOD OF PROCEDURE

The council might consider any problem submitted by a member society, or its representative, that might in any manner affect organized medicine or public health in New England, or in any part of New England. A majority vote might be deemed sufficient to pass any measure, but all council legislation might be submitted to the governing body of each constituent society for action. If one or more of these bodies rejected any measure in a stated time from the date the report of the measure is made by the secretary of the council, the measure then might be reconsidered at the next meeting of the council. If, at such subsequent meeting the measure was passed by a two-thirds vote of the council, it would then become a council act

The council might also serve well as a body, to initiate studies on problems of mutual interest to the member societies—for example, plans and programs for voluntary medical care, group hospitalization, participation in federal-state programs, postgraduate medical education, public relations relative to the problems of organized medicine, national and local health legislation, development of the medical publications within the various states and the assignment of meeting dates to eliminate conflicts in securing guest speakers and in procuring technical exhibits

OFFICERS FOR 1945-1946

- PRESIDENT Reginald Fitz, Brookline Office, Boston (15), 319 Longwood Avenue

STANDING COMMITTEES FOR 1945-1946

(ELECTED BY THE EXECUTIVE COMMITTEE OF THE COUNCIL, MAY 23, 1945)

ARRANGEMENTS — Established 1849

	<i>Date of Appointment</i>
Roy J Heffernan, Norfolk, Chairman	May 25, 1942 (appointed chairman May 22, 1944)
G Guy Bailey, Jr, * Middlesex South	November 13, 1942
Harold G Giddings, Middlesex South	May 22, 1944
Robert L Goodale, Suffolk	May 22, 1944
Sidney C Wiggan, Suffolk	June 24, 1942

ETHICS AND DISCIPLINE — Established 1871

Ralph R Stratton, Middlesex East, Chairman	June 9, 1936 (appointed chairman May 21, 1941)
William J Brickley, Suffolk	February 3, 1937
Archibald R Gardner, Middlesex North	May 21, 1941
Fred R Jouett, Middlesex South	May 21, 1940
Allen G Rice, Hampden	June 1, 1938

FINANCE — Established 1938

Francis C Hall, Suffolk, Chairman	July 8, 1943
Ernest L Hunt, Worcester	June 2, 1938
Edward J O'Brien, Jr, Middlesex South	June 2, 1938
Peer P Johnson, Essex South	October 4, 1939
Charles F Wilinsky, Suffolk	June 2, 1938

INDUSTRIAL HEALTH — Established 1942

Thomas L Shipman, Essex South, Chairman	May 25, 1942 (appointed chairman [interim appointment] June 29, 1945)
Joseph C Aub, Suffolk	May 25, 1942
Louis R Daniels, Middlesex South	May 22, 1944
John G Downing, Middlesex South	May 22, 1944
Patrick E Gear, Hampden	May 23, 1945
Harold R Kurth, Essex North	May 23, 1945
Daniel L Lynch, Norfolk	May 25, 1942

MEDICAL DEFENSE — Established 1927

Arthur W Allen, Suffolk, Chairman	June 7, 1927 (appointed chairman June 7, 1939)
Ira M Dixon, Berkshire	August 17, 1942
Edwin D Gardner, Bristol South	June 7, 1927
William R Morrison, Suffolk	June 9, 1936
Horatio Rogers, Suffolk	June 7, 1939

MEDICAL EDUCATION — Established 1881

Robert T Monroe, Norfolk, Chairman	May 21, 1941 (appointed chairman February 4, 1942)
Arthur W Allen, Suffolk	May 24, 1943
George D Henderson, Hampden	June 1, 1938
Isaac R Jankelson, Norfolk	May 25, 1942
Chester S Keefer, Suffolk	February 4, 1942

*Italics indicate that the physician is not a member of the Council of the Society

MEMBERSHIP — Established 1897

- Harlan F Newton, Suffolk,
Chairman
June 9, 1931 (ap-
pointed chairman
May 25, 1942)
Roy V Baketel, Essex North
January 10, 1945
William A R Chapin, Hampden
May 23, 1945
Perce H Leavitt, Plymouth
June 1, 1938
Samuel N Vose, Suffolk
March 15, 1944
William H. Allen (Bristol North), H Quimby Gallupe (Mid-
dlesex South), Albert E Parkhurst (Essex South), represent-
ing the Supervising Censors

PUBLICATIONS — Established 1825

CASE 31301

PRESENTATION OF CASE

First admission. A sixty-five-year-old police chief was admitted to the hospital because of jaundice, chills, malaise, nausea and vomiting.

The patient had always been well and active until about five months before entry, when his urine became dark, one week later the scleras and face became slightly yellow. He continued to feel well and worked until about three weeks after the onset of jaundice, when one day he had a chill, slight fever, malaise and that night was nauseated and vomited. There was no pain. Soon after that episode he became markedly jaundiced. He was admitted to a community hospital for a period of two weeks, during which time the urine remained dark, the stool became clay-colored and the deep jaundice persisted. The patient left the hospital on a fat-free diet, feeling much better, the stools were yellow, but the jaundice remained and pruritus became marked. At home he remained quite well and without much change until one month before admission, when fairly severe malaise reappeared, which persisted until five days before admission. Two weeks before admission he began to have a "dull soreness" in the right upper quadrant, this extended to the left upper quadrant and was associated with transient sharp shooting pain in the same region and also in the region of the left scapula. These pains were almost constant during the two weeks before admission and were severest after meals. During the month before admission the jaundice gradually became less intense and the urine became lighter in color, the stools at the time of admission were of normal color. During this five-month illness his weight had fallen from 235 to 186 pounds. He had no awareness of food intolerances. He never drank alcoholic beverages.

The patient's father, one of six sisters and one of two sons had died of tuberculosis.

Physical examination revealed a markedly jaundiced, well developed man showing evidence of recent weight loss. The heart and lungs were normal. The abdomen was flat and soft. The right lobe of the liver was palpable three fingerbreadths

below the costal margin and presented a smooth even edge. The upper border was percussed at a normal level. The left lobe was apparently not enlarged by percussion posteriorly. In the mid-epigastrium, extending from the tip of the xiphoid halfway to the umbilicus was a round firm nontender mass about 5 cm in diameter. It descended with inspiration and was indistinguishable from the liver.

The temperature, pulse and respirations were normal. The blood pressure was 130 systolic, 68 diastolic.

Examination of the blood showed a white-cell count of 6400, with 64 per cent. neutrophils, and 10.5 gm of hemoglobin. The urine was light amber and contained no bile, the sediment showed 15 red cells and a rare white cell per high-power field. Several stools were brown and guaiac negative. The blood Hinton test was negative. The serum non-protein nitrogen and protein were normal. A van den Bergh showed 2.9 mg of bilirubin direct and 3.3 mg indirect. The prothrombin time was 21 seconds (normal, 18 to 20 seconds). A bromsulfalein test was normal.

By x-ray examination the liver and spleen were thought to be of normal size. No unusual areas of calcification were seen. A Graham test did not outline the gall bladder. On the third day a peritoneoscopy showed that the left lobe of the liver and the region of the mass were concealed by adhesions of the omentum to the anterior abdominal wall that obliterated almost the entire left upper quadrant. The right lobe of the liver was readily seen. The edge appeared rounded and smooth, it was grayish, with a slightly thickened capsule. No nodular areas were seen. There was no fluid, and the serosa was smooth. A gastrointestinal series showed a normal esophagus. In the fundus of the stomach, extending from the cardia upward and lying somewhat anteriorly, there was a defect by what appeared to be a large soft-tissue mass (Fig 1). The mucosal pattern was not definitely traceable through this region. The edges of the defect were quite sharp. A seemingly distinct and definitely extrinsic mass was seen pressing on the lesser curvature of the stomach somewhat anteriorly. This represented the mass palpable in the abdomen. Barium passed through the pylorus without hesitation and filled the duodenal bulb. The duodenal loop appeared smaller than usual, and the mucosal pattern was everywhere normal.

The patient was given a transfusion, and on the tenth day an exploratory laparotomy was performed. The omentum was found to be densely adherent to the anterior surface of the liver. The tumor could be palpated and was believed to lie in the stomach, although the latter was not visualized in the region of the tumor. An opening was made through the gastrocolic omentum, and the posterior surface of the stomach was explored. No

*On leave of absence.

adhesions were found there. The mass was then investigated, and on attempting to dissect away the omentum, a large subdiaphragmatic abscess was found. An extensive prophylactic drainage was deemed necessary and was performed. A culture of the abscess showed a moderate number of colonies of nonhemolytic streptococci and a few of colon bacilli. The prothrombin time was 30 seconds and over a two-week period fell gradually to 22 seconds. The van den Bergh test became too low to read. Cephalin flocculation tests were +++ to +++++, and a bromsulfalein test showed 30 per cent reten-

On physical examination he was found to be jaundiced. The sinus was draining a moderate amount of reddish-brown pus. The left lower chest was dull and showed diminished breath sounds and tactile fremitus. A friction rub was heard in the left chest anteriorly. The abdomen was soft, the liver and spleen were not felt. The epigastric mass appeared to be the same as on the first admission.

The temperature, pulse, and respirations were normal.

The urine was normal. The white-cell count was 11,200, with 62 per cent neutrophils, and the

FIGURE 1

tion thirty minutes after 2 mg of dye per kilogram of body weight had been injected.

The patient remained asymptomatic, with a good appetite, and only the drain in the left gutter continued to discharge. He was discharged to his home on the twenty-ninth postoperative day, with arrangements to return in three weeks for removal of the gastric lesion.

Second admission (one month later). During the interim the patient had been well, his appetite was good, he slept well, and there was no recognized recurrence of the jaundice. Two days before admission he had an episode of nausea and vomiting followed by a day of anorexia.

hemoglobin 10.7 gm. A repeat Hinton test was negative. A bromsulfalein test now showed 15 per cent retention in thirty minutes, and a van den Bergh test was 1.3 mg direct and 1.9 mg indirect. The prothrombin time was normal. X-ray examination of the chest showed a moderate amount of fluid in the left pleural cavity. The lung fields were clear. The heart and mediastinum were not displaced. The heart and right diaphragm were normal. The left half of the diaphragm was obscured by fluid and showed limited excursion. A plain film of the abdomen showed no enlargement of the liver. The spleen was not seen. The defect in the air-filled cardiac portion of the stomach was sepa-

rated from the diaphragm by approximately 5.5 cm. No gall-bladder calculi were seen. A gastrointestinal series was not significantly different from the former one. The patient was discharged on the third day.

Third admission (five weeks later) Following discharge he had felt well and strong. Two and a half weeks before admission he ate a fatty meal, which was followed by an episode of nausea and vomiting. There had been no weight loss.

Physical examination revealed the jaundice to be somewhat improved although still present. The liver was a little larger than previously, but the epigastric mass appeared unchanged. There were a few moist rales at the left base posteriorly, as well as a small area of dullness. The sinus was still draining.

The temperature, pulse, respirations and blood pressure were normal.

The urine was normal except for the presence of urobilinogen in a dilution of 1:50. The white-cell count was 7600, with 72 per cent neutrophils, and the hemoglobin 10.9 gm. A stool was normal. The prothrombin time was 23 seconds. A gastrointestinal series suggested that the mass in the fundus of the stomach was somewhat smaller than at the last examination. Some fluid remained in the left costophrenic sinus, but the amount had markedly diminished.

The patient was given two whole-blood transfusions, and on the sixth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR ROBERT R. LINTON This case is puzzling to me. There is no question that this man had an upper abdominal lesion and it is up to me to try to make a diagnosis. As one reads the record it is obvious that the patient had a subdiaphragmatic abscess on the left side. It is important to note that he had been sick for a considerable period — four or five months. The presenting symptom when he first came in, in addition to general malaise, nausea, chills and vomiting, was jaundice of several months' duration. The striking thing about the jaundice is that it was of an intermittent type, despite the fact that nothing was done to the biliary system to try to relieve it. I am a little disappointed that in the operative note no mention is made of the gall bladder. I presume that it was not seen because it was involved in the inflammatory mass.

DR BENJAMIN CASTLEMAN Dr Sweet, can you answer that?

DR RICHARD H. SWEET We thought about the gall bladder but my attention was centered on the two masses — the one high in the fundus of the stomach and the one that turned out to be a subdiaphragmatic abscess. I palpated the gastric mass first and formed some judgment about that. Then I explored the midepigastric mass and immediately broke into pus. I made no effort to see the gall bladder.

DR CHESTER M. JONES The mass that you broke into was a tremendous one?

DR SWEET Yes — a huge abscess.

DR LINTON The laboratory studies do not help at all in the diagnosis.

There is a family history of tuberculosis, but I do not believe that his condition was due to an acid fast infection.

It is rather surprising, in view of the subphrenic abscess, that this man did not have more fever. The temperature was normal throughout the course in the hospital. Furthermore, he had no leukocytic response to the abscess.

DR JONES Those things bothered us, too.

DR LINTON One of the conditions that I have to consider is pancreatitis. That seems unlikely in view of the fact that the lesser peritoneal cavity did not appear to be involved by the inflammatory mass at the time of exploration, as I understand it. Since the pancreas lies in the lesser peritoneal cavity, I should think that, if he had had a pancreatitis, it would have been obvious.

I should like to see the x-ray films.

DR GEORGE W. HOLMES The upper film shows the stomach fairly well, and it is obvious that there is a large pressure defect on the lesser curvature and another in the region of the fundus. It would be helpful if I could say whether the stomach was actually involved, that is, whether the ulcer crater went out into this area, but I cannot. From the reports, the man who did the examination thought that there was actual involvement of the stomach. Of course, in a picture like this, one thinks of sarcoma, but we have insufficient proof to make such a diagnosis. An attempt was made to show the gall bladder, but apparently it did not fill with the dye.

DR LINTON They did a gastrointestinal series later. Are those films here?

DR HOLMES Yes, but so far as the stomach is concerned there has not been any great change. There is something here that might be said to be a mass inside the stomach, which was not there before. I should like to know whether it was food or whether it was a mass. It could be either. If it was a mass, it means that whatever it was had extended into the stomach.

The chest may be of some interest. I should say that it was quite normal. It certainly does not show anything except a high diaphragm on the left.

DR LINTON I believe that the findings in the chest, as reported in the history, indicate an inflammatory process in the upper abdomen. I do not believe that he had a primary condition within the chest, and anything seen by x-ray is probably secondary to the subphrenic abscess. Is it possible that this man had a liver abscess, which could explain the jaundice and also, possibly, the subphrenic abscess? It seems unlikely because I do not believe

at a patient with a liver abscess would run a normal temperature and have a normal white-cell count. I so think that it would be unusual to have an intermittent type of jaundice, unless the liver abscess self were drained.

It seems to me that we are probably dealing with primary lesion in the stomach that had perforated into the upper abdominal cavity and had formed an abscess. The cultures are slightly in favor of an intestinal lesion that had perforated in view of the fact that they contained not only nonhemolytic streptococci but also colon bacilli.

Is it possible that this man had a perforated gastric ulcer? That seems quite unlikely in view of the fact that no lesion of that nature was seen by x-ray.

Another possibility, of course, is that this man had carcinoma of the stomach, with metastases beneath the diaphragm. There are some lymph nodes in that region, which, if enlarged, might have pressed down on the stomach. There is a possibility of lymphoma, but I do not know any way of making that diagnosis.

In summary, I favor an upper gastric lesion, probably a malignant tumor. This had perforated, and the abscess was drained, later an operation was done in an attempt to remove the lesion.

DR CASTLEMAN: How do you account for the jaundice?

DR LINTON: The only way that I can account for it is that the inflammatory mass must have produced pressure on the biliary system, which caused jaundice, when the inflammatory mass was drained, this relieved the pressure on the common duct.

DR CASTLEMAN: Dr Jones, will you give a brief summary of your observations on this man?

DR JONES: I saw this patient when he first came in. He was definitely jaundiced and had a tremendous nontender mass in the midepigastrium. With the story of the jaundice I thought, and subsequently Dr Sweet agreed, that the most reasonable diagnosis was malignant disease, with metastases to the liver that caused pressure on the bile duct. As we studied him, however, many queer things came to light that warranted exploration. The x-ray studies were quite striking. The pressure on the lesser curvature was obviously produced by the palpable mass. Then the finding of something additional in the stomach bothered us a great deal. Another thing that bothered us was the complete absence of fever and leukocytosis. It was striking that he continued to run an afebrile course, and so far as we could tell he had not had a fever before he came into the hospital. He was explored in the hope that we might find a situation that we could remedy, but with the thought that malignancy might be encountered.

At the first operation a subdiaphragmatic abscess was found, which explained the pressure on the lesser curvature of the stomach, and at the same

time Dr Sweet was able to palpate the stomach. That was as far as we were able to go. We thought, therefore, that we should give the patient a chance to recover from the first operation and then go in a second time for further examination of the stomach. We went over the x-ray films many times and wondered whether a leiomyosarcoma of the stomach was the explanation for the gastric mass. At the same time we were fairly sure that, since a subdiaphragmatic abscess had been found, it was not reasonable to assume that a gastric tumor was the cause. In other words, there might have been a primary cause for the jaundice and the subsequent subdiaphragmatic abscess. Even before the second operation we both decided that eventually the biliary tract had to be explored but that it could not be done at the second operation.

DR SWEET: As I have said, at the first operation I obtained an impression from feeling the gastric lesion, I thought that it was probably a leiomyosarcoma. It was a round hard mass which I could not see but could feel. The x-ray appearance also suggested that rather than carcinoma. The first operation was done with the thought that there might have been metastases to the liver, but none were found.

The second procedure was done through the chest, and I found a large hard round mass that was not easy to free because of the adhesions from the previous inflammatory process. It was obvious, ultimately, that this mass was not part of the stomach, it looked like spleen, although it had a peculiar shape. There was a normal-looking spleen, which I did not disturb. I took out the large mass.

CLINICAL DIAGNOSIS

Leiomyosarcoma of stomach?

DR LINTON'S DIAGNOSIS

Malignant tumor of stomach, with perforation

ANATOMICAL DIAGNOSES

Accessory spleen

Cholelithiasis

PATHOLOGICAL DISCUSSION

DR CASTLEMAN: I am afraid that we have made Dr Linton "the goat" for the sake of presenting an unusual condition. This peculiar mass proved to be an accessory spleen showing no abnormality microscopically. There was an acute perisplenitis and a subdiaphragmatic abscess.

DR LINTON: Is that not an unusual place for an accessory spleen?

DR CASTLEMAN: It is quite unusual, and it was the largest one that I have ever seen. It was not perfectly round. It had somewhat the shape of a normal spleen but did not have a hilus. The accessory spleen that one ordinarily sees is roughly 1 to

2 cm in diameter and perfectly round This one measured 12 by 7 by 5 cm

Will you tell us about the postoperative course, Dr Jones?

DR JONES We thought that we still had to go after the original cause and that the gastric lesion was a red herring, so to speak, being simply an interlude in a long story

In the next six months the patient gained a great deal of weight and was in relatively good condition He was jaundiced all the time, although at times clinical icterus was just barely present Repeated tests showed that he was having a gradual increase in hepatic involvement, in the sense that the dye retention slowly went up It is of interest that during this period the epigastric mass reappeared We attributed this to a gradual increase in the size of the left lobe of the liver to normal proportions, which it turned out to be at operation While he was being followed, the alkaline phosphatase rose steadily, reaching 30 Bodansky units per 100 cc, which practically always means biliary-tract obstruction, this is frequently due to a malignant tumor, although it can go as high as that with stone in the common duct The third operation was performed with the idea that the common duct and gall bladder should be explored, we thought that a stone would be found as the cause of the original jaundice and the other symptoms

DR SWEET At the final operation we explored the biliary tract, which was rather difficult of access because of the previous inflammatory process The common duct was immensely dilated, and on opening it I found a large stone lodged near the ampulla That was removed with ease, and no other stones were found The gall bladder was small, no longer than 2 cm, and had hardly any lumen At that time I saw no definite evidence of perforation, but I assumed that the abscess had resulted from a perforation of the gall bladder rather than from a perforation of the common duct

DR CASTLEMAN How did the liver look?

DR SWEET It was large and had a peculiar shape, the portion to the left of the ligament being much larger than that on the right, it was round and had a rather rough surface The spleen was palpated in its normal position

DR CASTLEMAN Biopsy of the liver showed an obstructive biliary cirrhosis

DR JONES There is one more point After the third operation the patient again became deeply jaundiced, but that subsequently receded, with gradual improvement in the bromsulphalein retention test Even now, however, two months later, the phosphatase has not returned to normal It takes many months for that to return to normal in cases of incipient biliary cirrhosis

DR WYMAN RICHARDSON Perhaps the white-cell count was normal because he had too much spleen How is that for a theory?

DR HOLMES We should have paid more attention to the fact that the Graham test did not visualize the gall bladder

CASE 31302

PRESENTATION OF CASE

A fifty-one-year-old brass grinder was admitted to the hospital because of dyspnea, cough and substernal pain

Five weeks before admission, on the way home from his laborious work, he developed a heavy feeling in his epigastrium that he thought was due to a cold For the first time he experienced shortness of breath, which progressed in severity despite constant bed rest The epigastric discomfort was not related to effort An irritating cough was at times productive of thick whitish sputum Associated with the epigastric discomfort, he also had an episode of chills, sweating and a fever up to 102°F, which lasted for five days Two and a half weeks before admission, there was a recurrence of chills and fever During the two weeks before entry he had episodes of severe nocturnal dyspnea, but with sedation and two to three pillows he slept well He had been allegedly digitalized before admission

Five years before admission he had passed a life insurance examination Two years before admission he had been treated for hypertension and headaches He had been a brass grinder for two years, working in poorly ventilated, dusty quarters

Physical examination revealed a well developed and nourished man in moderate respiratory distress, with fairly marked orthopnea The neck veins were slightly dilated when he lay flat Diffuse moist rales were heard throughout the chest, most marked at the left base The heart showed normal rhythm at a rate of 120 The point of maximal impulse was thought to be somewhat displaced to the left There was a coarse Grade-4 "wood-sawing" systolic murmur well transmitted to the back, as well as an early high-pitched diastolic murmur at the apex There was also a Grade-1 pulmonic systolic murmur with an accentuated second pulmonic sound, which was louder than the aortic second sound Pulsus alternans and an occasional third heart sound were detected Examination of the abdomen was negative The liver and spleen were not enlarged The extremities were slightly cyanotic

The temperature was 101.5°F, the pulse 120, and the respirations 30 The blood pressure was 130 systolic, 90 diastolic

Examination of the blood showed a red-cell count of 4,400,000, with 11.2 gm of hemoglobin, and a white-cell count of 6000, with 54 per cent neutrophils The urine had a specific gravity of 1.024 and was normal The serum nonprotein nitrogen was

mg per 100 cc., and the carbon dioxide 24.3 milliequiv per liter. An electrocardiogram showed sinus tachycardia at a rate of 125, a PR interval 0.16 second, a sagging ST₁, a slightly elevated S₁, a small S₂ and an inverted T₂ and T₃. There were prominent T waves in Leads CF₃, CF₄ and F₁, and sagging ST segments in Leads CF₄ and F₁. Q₁ measured 4 mm. By fluoroscopy the heart beat normally and both halves of the diaphragm showed limited motion.

An x-ray film of the chest showed the heart to be within normal limits, the cardiac-thoracic ratio being 13.5:29.0 cm. There was definite prominence of the left auricle, particularly posteriorly. There were flocculent areas of increased density scattered throughout both lung fields, more marked centrally and extending from the hilar shadows into the lung fields. There was no evidence of fluid on either side.

Repeated blood cultures showed no growth. The white-cell count rose to 11,000 on the fifth day and then remained unchanged. Throughout the patient's hospitalization the temperature was elevated to about 101°F every evening and returned to almost normal by morning. The pulse was erratic between 90 and 120. The respirations varied from 20 to 45. Fluid intake and output were low. He was maintained on digitalis and ammonium chloride. On the second day the blood pressure fell to 95 systolic, 60 diastolic, and remained at about that level until death. An x-ray film of the chest on the third day was unchanged. During the night and during periods when the heart rate was rapid, the sounds were poor and the patient became quite dyspneic. On the sixth day he coughed up bright-red rather frothy sputum, without chest pain of any sort. He remained dyspneic, and at that time high-pitched rales were heard at both bases and in the axillae. Another electrocardiogram on the sixth day showed no change. On the twelfth day he complained of some precordial pain. He was not orthopneic. He preferred to lie on his right side, with his head over the edge of the bed, and claimed that he felt better in that position.

On the thirteenth day the patient suddenly became critically ill, complaining of substernal distress. The blood pressure fell to 70 systolic, 50 diastolic, the pulse increased to 176 and was mildly irregular, and the respirations rose to 60. He was cyanotic, cold and clammy. The lungs filled with moist rales. After the administration of Cedilanid, aminophylline and oxygen and the application of tourniquets he improved, but the pulse and respiratory rates remained high. The chest pain became more pronounced, and the respirations became irregular and eventually ceased.

DIFFERENTIAL DIAGNOSIS

DR. EDWARD O. WHEELER: This man died about seven weeks after the onset of an acute illness

characterized by chills, fever, shortness of breath and cough. Because of his occupation—he was a brass grinder—the question comes up whether this played any part in his illness. Did he have silicosis? He was working in poorly ventilated quarters exposed to dust. Two years is a relatively short period of exposure, but if he were working in a place where the concentration of silica in the dust was high, he might have developed this disease. Certainly the symptoms of shortness of breath and cough are consistent with silicosis. One does not see chills and fever, however, in uncomplicated silicosis. If he had a bronchopneumonia or tuberculosis along with the silicosis, he might have had chills and fever, and this would also explain the short duration of the illness. The loud systolic murmur and the symptoms of left ventricular failure are not, however, explained by this disease. Patients with a marked degree of silicosis occasionally develop chronic cor pulmonale, but this does not often occur. The electrocardiogram should help in making this diagnosis. As recorded in the protocol, the S₁ and Q₁ and the inverted T₂ and T₃ are slightly suggestive of right ventricular strain. Is the electrocardiogram here?

DR. BENJAMIN CASTLEMAN: You may see the one in the record.

DR. WHEELER: There is not much in this tracing to suggest right ventricular hypertrophy. There is no evidence of axis deviation, which is helpful because it tends to rule out aortic-valve disease and hypertensive disease, that is, conditions resulting in left ventricular hypertrophy. Because of the Q₁ and the inverted T₂ and T₃ he might have had a posterior myocardial infarct, but there is no change in the electrocardiogram taken six days later, furthermore, the absence of a Q₂ is against this diagnosis. I understand that the x-ray films are missing, which is unfortunate, for they might have helped a good deal in making the diagnosis.

DR. CASTLEMAN: Dr. Gardella, could you describe the films?

DR. J. WARREN GARDELLA: They are quite well described in the written report. There were flocculent areas radiating from the hilus of each lung.

DR. WHEELER: Did the X-ray Department think that this represented consolidation or pulmonary edema?

DR. GARDELLA: They were unable to say. The areas of flocculation were well defined and rather centrally located in both lung fields. The process was more marked on the right than on the left.

DR. WHEELER: The findings are suggestive of pulmonary edema, although the history is not that of a failing heart with pulmonary edema secondary to myocardial infarction.

DR. GARDELLA: I thought it significant that, despite the fact that he improved clinically so far as the heart and rales were concerned, the x-ray

picture remained the same. We then brought up the question of pneumoconiosis.

DR WHEELER The x-ray films were more suggestive of pulmonary edema than of pneumoconiosis, but I suppose that both might have been present.

To return to the findings in the heart, which are not explained by silicosis, it is said that he had a Grade-4 apical systolic murmur well transmitted to the back. That seems to indicate that he had mitral regurgitation. Aortic systolic murmurs are occasionally well heard at the apex but are not well transmitted to the back, as this murmur was.

It is interesting to note that five years before admission he passed a life-insurance examination, which suggests that the murmur was not present at that time. Two years later he was treated for hypertension. I do not know how to interpret the early high-pitched diastolic murmur at the apex, for the diastolic murmur due to mitral disease is low pitched rather than high and occurs in middiastole rather than in diastole. An aortic diastolic murmur might be transmitted to the apex, in which case it would be heard as an early high-pitched diastolic murmur, but usually such a murmur is better heard along the left sternal border. Then it is noted that the pulmonic second sound was increased, which, together with a pulsus alternans and gallop rhythm, indicates left ventricular failure, despite the fact that x-ray examination showed the heart to be normal in size. The x-ray films did show prominence of the left auricle, which is consistent with mitral disease.

In trying to tie in the cardiac findings with a febrile illness the first possibility that comes to mind is bacterial endocarditis, which can produce chills and fever and can cause death in a short time if congestive failure is present. An attractive possibility is that the patient developed subacute bacterial endocarditis on the basis of minimal rheumatic mitral disease, followed by rupture of a chorda tendinea, with the increased murmur and congestive failure. The difficulty in making that diagnosis is that the blood cultures were negative. Negative blood cultures, however, do not rule out subacute bacterial endocarditis.

I believe that hypertensive heart disease and chronic cor pulmonale are well ruled out. Could the patient have had a myocardial infarction five weeks before entry, which caused congestive failure and was associated with a pulmonary infection? That is a possibility. Such a condition might have caused left ventricular dilatation and a systolic murmur at the apex. Because of the electrocardiographic findings, however, it does not seem likely.

Then there are rare conditions that should be considered. This man might have had a virus infection with an associated myocarditis, but that is an unlikely possibility. There was no good evi-

dence of consolidation in the lungs, except for the fact that the pulmonary process did not clear up. On the other hand, pulmonary edema is frequently chronic and does not improve.

The best diagnosis I can make is subacute bacterial endocarditis superimposed on minimal rheumatic mitral disease, with an increase in mitral insufficiency, due to valve deformity or a ruptured chorda tendinea, leading to congestive failure and death.

CLINICAL DIAGNOSES

Coronary heart disease
Pulmonary edema
Pulmonary infarction?

DR WHEELER'S DIAGNOSES

Subacute bacterial endocarditis
Rheumatic heart disease, with mitral insufficiency
and possibly a ruptured chorda tendinea
Congestive failure, with pulmonary edema

ANATOMICAL DIAGNOSES

Coronary thrombosis, old and recent
Myocardial infarction of papillary muscle, healing, with deformity of mitral valve
Myocardial infarction, old posterior wall of left ventricle
Organizing pneumonitis, with extensive intra-alveolar fibrosis all lobes

PATHOLOGICAL DISCUSSION

DR CASTLEMAN The autopsy on this man showed a large heart, which weighed almost 500 gm. There was a bulge of the myocardium in the region of the posterior wall, which, when the heart was opened, proved to be a cardiac aneurysm (healed myocardial infarct). In places the wall was extremely thin, measuring only 2 mm. On the endocardial surface of this large, old infarct, which measured 6 by 4 cm, was an organized mural thrombus. The papillary muscle, which arises just above that point, was instead of the usual thick muscle bundle an extremely thin slightly fibrous band. This band had pulled away the posterior leaflet of the mitral valve so that when the valve closed it was incompetent. This thinning out of the papillary muscle was due to recent infarction at its base. So, although there was no bacterial endocarditis, the same principle was involved, that is, the infarct produced an effect that was tantamount to rupture of the muscle. The process was beginning to heal, and I believe that it was of about five weeks' duration. Rather far down in the right coronary artery there was an old thrombosis, which accounted for the healed infarct, as well as a more recent thrombus proximal to the old lesion. Perhaps the electrocardiogram did indicate posterior myocardial infarction.

he lungs were interesting, but I am not at all
an that I can fully explain the lesion. All five
s presented a similar appearance, being big
wet and weighing 2000 gm (normal, less than
1000 gm). On section the surfaces were gray and
nular. The process did not look like a true lobar
pneumonia or pulmonary edema but seemed to
be somewhere between the two. Microscopically
there were organizing fibrous tissue plugs in many
of the alveoli, alveolar ducts and respiratory
bronchioles. This picture was present in every lobe
of the lung. The only explanation I have for it is
that it represents an organizing unresolved pneu-
monia that began five weeks before entry, probably
the same time as the coronary thrombosis. There
are no fibrous plugs in the large bronchioles, so
that it cannot be called bronchiolitis fibrosa ob-
literans. In some alveoli we found fat-laden phago-
cytes and giant cells. There was no evidence, how-
ever, of tuberculosis or silicosis. This pulmonary
lesion reminds me of a case previously reported

here¹ in which there was a large thrombus in the
left auricle that obliterated the orifices of the pul-
monary veins of one lung, which showed a similar
alveolar fibrosis. It is quite possible that the in-
competence of the mitral valve, owing to the in-
farction of the papillary muscle, predisposed the
lung to develop this organizing process. This pic-
ture has been described by Masson² as a characteris-
tic feature in rheumatic pneumonia.

DR WHEELER: Rupture of a chorda tendinea
can occur spontaneously or with endocarditis, but
rupture of the papillary muscle almost always occurs
in infarct and leads to death within two or three
months, with congestive failure.

DR CASTLEMAN: This patient did not have com-
plete rupture.

INCREASING AND MAINTAINING PENICILLIN BLOOD LEVELS

MANY methods have been recommended for delaying the absorption or the excretion of penicillin with the idea of maintaining high levels in the circulating blood for longer periods than are possible with simple injections of penicillin solutions. Such an effect is obviously desirable in certain subacute or chronic infections, such as syphilis, subacute bacterial endocarditis and osteomyelitis, that require treatment over long periods. Furthermore, the organisms in such cases often are not highly sensitive and, therefore, require greater concentrations than those that can be conveniently maintained by ordinary interrupted intramuscular

injections — and the use of continuous intravenous or intramuscular injections to accomplish this purpose is cumbersome and somewhat wasteful.

The methods for prolonging penicillin action have been reviewed and commented on recently in these columns.¹ Among those that seemed feasible and effective was the use of para-aminohippuric acid by constant intravenous infusion. This compound acts like Diodrast or other similar substances, apparently competing with the penicillin for excretion by the kidney tubules. Although para-aminohippuric acid is said to be nontoxic in the doses used and to be well tolerated for long periods, it has the undesirable features of any therapy that must be given by constant intravenous injection.

Bronfenbrenner and Favour² at the Peter Bent Brigham Hospital attempted to accomplish the same purpose with oral therapy. They utilized the principle involved in one of the well known liver function tests, namely, the conjugation of orally administered benzoic acid by the liver into hippuric acid and the excretion of the latter into the urine. Since the penicillin blocking power of benzoic acid was relatively small on an unrestricted diet, they combined a regime of fluid and salt restriction with the benzoic acid therapy. They also tried sodium benzoate but found that the added base tended to neutralize the effects of the controlled salt intake, and in addition, the dose of sodium benzoate given proved to be somewhat nauseating. On a normal diet 2.5 gm of benzoic acid was equivalent to 60 gm of sodium benzoate in raising penicillin levels.

The regime finally adopted consisted of keeping the daily caloric intake between 1500 and 2000 calories. The diet was otherwise restricted only by limiting the fluid intake to between 1000 and 1500 cc a day, and the salt to 3 gm or less a day. This gave a daily urinary output of 400 to 600 cc. The dose of benzoic acid was about 2.5 gm every four hours, either disguised by mixing it with food or given in four capsules of 0.6 gm each. Most patients preferred the latter. The benzoic acid was given twenty to thirty minutes before the intramuscular injection of penicillin. On the basis of observations in 6 patients these workers found that restriction of fluid intake to 1500 cc and of the salt intake to 3 gm a day doubles the penicillin blood level follow-

interrupted intramuscular injections of penicillin, the administration of benzoic acid to a patient on an unrestricted diet may double the usual penicillin blood level during similar treatment and that combination of these two procedures results in four-fold to eight-fold increase in penicillin blood level, with a prolonged effective blood concentration. This method is obviously simpler than its counterpart that requires constant intravenous injection of para-aminohippuric acid. Whether it will prove more useful than other methods, such as the intramuscular injection of penicillin in beeswax and peanut oil,³ remains to be seen. Both methods are worthy of clinical trial.

HEALTH IN EUROPE

An attempt has been made in the March, 1945, issue of the *Statistical Bulletin* of the Metropolitan Life Insurance Company to evaluate the 1944 health conditions on the Continent. Various estimates of the European morbidity and mortality from causes other than violence have been put forward from time to time, but the figures are largely a matter of guesswork. Information on which the present study is based is fragmentary, being derived from several sources, chiefly the weekly epidemiological record of the Health Section of the League of Nations.

The situation in Germany showed signs of increasing deterioration, if the mortality from tuberculosis is assumed to be the best available index, there was an increase of about one third for the first quarter of 1944, compared with the first quarters of 1938 and 1939. Numerous cases of typhus fever occurred, cerebrospinal meningitis continued to be prevalent, and in the first nine months of the year about 200,000 cases of diphtheria were reported.

Typhus fever was also found to be prevalent in Holland, and in the liberated portion of Belgium the death rate was 22 per cent higher in October, 1944, than in the same month of 1943. Health conditions apparently remained fairly good in Den-

mark, although in both Denmark and France epidemic influenza was prevalent. The tuberculosis mortality in Paris showed a high level throughout the German occupation.

The record has been bad in Italy, even in the liberated portion, the death rate in Rome being reported as 17.7 per 1000, or more than 60 per cent above the 1940 rate. No figures are available for Poland, the unhappy country that has perhaps suffered more from foreign domination than has any in history. The incidence of typhus fever has remained high in the Balkan states. Tuberculosis is said by relief officials to have reached epidemic proportions in Greece, and in mid-1944 about 70 per cent of its population was reported to be suffering from malaria.

These estimates were collected and published prior to the collapse of Germany. Much more recently has come a report from Major General Warren Draper, deputy surgeon general of the United States Public Health Service and chief of the military government public-health branch of SHAEF in Paris, indicating that the health of both liberated countries and occupied Germany is not only "far better than generally supposed, but in many respects apparently approaching a normal peacetime standard." According to General Draper, however, the days ahead will be grim ones nutritionally for Europe, because of the disruption of normal supplies. One cannot help but wonder why, with the war over and millions of men released for productive labor, conditions should be so much worse for Europe generally than they were under nearly five years of German domination.

MASSACHUSETTS MEDICAL SOCIETY

PRESIDENT'S REPORT ON THE STATE OF THE SOCIETY*

ASSUMPTION and carrying of the leadership of this society bring a true comprehension of the potential activities and services that have not been initiated or developed. These war years have absorbed the available energies of every fellow of the Society. Nevertheless, I have been stimulated by the unselfish response of the busiest men in the

*An address delivered at the meeting of the Executive Committee of the Council of the Massachusetts Medical Society in lieu of the annual meeting of the Council, Boston, May 23, 1945.

Society to the invitation to service on committees Without this loyal support, the efforts of its leaders could accomplish little

The president of the Massachusetts Medical Society now spends about half his energy and time in performance of fundamental obligations of the office. The obligations of the office have priority over ordinary demands of practice. One of my friends said the other day that the Society ought to elect a retired fellow as president so as not to take the time of an active physician, but the job needs the energy and enthusiasm of a relatively young man, and he needs all the help that he can find.

I am sure there is, even now, latent energy that could be activated and used in the Society's service. If the district nominating committees were well chosen and better informed, and if they took their obligations seriously, the state society would have even better executive, public relations, legislative and nominating committees. It is not enough to come to committee meetings. It is not enough even if you stay until the business is finished. You must, in addition, represent the group that sent you here, and moreover, you must represent the state society's point of view when you go back to your district.

One of my objectives has been to develop a more effective democracy in the Society. Every fellow has and *should exercise* his own share of the responsibility. Every district society should be an effective part of the organization. The central committees with district counterparts need the stimulus of initiative from the districts. The district public-relations committees have an obligation to meet the problems of socioeconomic public relations locally, as well as keeping the central committee informed, through the district chairmen, who are their delegates to the state committee, about their local problems and how they are met. Major principles of policy should be cleared through the central committee. Some districts have met and solved problems in a creditable manner but have not adequately reported their experience for the general benefit. Better liaison is needed between cities in the districts, as well as between the district and state societies. Parenthetically, effective interstate liaison offers tremendous values. It seems to me the time is ripe for revival of the New England Medical Council.

I hope that you will not feel it inappropriate for me to record here some personal impressions gained through a relatively active association with medical organization for many years and more especially in the last two years. I have taken my *ex-officio* membership in all committees seriously and have assimilated a point of view that seems worth reporting.

In the past two years a great many doctors have gotten out of the groove of subjective musing into the objective area of thinking and talking in fields relating to the distribution of medical care. There

is a little more evidence of individual initiative and of group initiative from district societies. Recently eighteen state-society presidents met in Michigan at the invitation of the Michigan State Medical Society to consider the desirability of co-ordinating grass-roots planning for realistic approach to problems of unmet needs.

There are some who look with misgiving at any departures from traditional policies. There are some who believe we should ruthlessly discard old ways. These divergencies are the essence of democracy. Leadership should not be too far behind new crystallizing attitudes of less vocal majorities. If the president of the Society can sense definite major trends and feels confident of majority support, he should exercise the initiative that I believe is given him by the Society when he is elected to lead. In these times the attitude of awaiting specific mandates from the formal vote of the Society may be much too slow. I have never hesitated too long to take an action that seemed to me to be in the Society's interest, despite the objections of some men whom I regarded highly. Personally, I believe the American Medical Association is a little too slow in adjusting its policies and activities to crystallizing opinion. The structure of democracy in the organization is there, but too few of the right men are vocal soon enough for efficient evolution. This also applies to society as a whole.

In a recent survey, less than half of twenty-two groups represented in the Massachusetts Central Health Council favored voluntary plans for medical care. How many of these groups have broad enough information to have well-grounded opinions? It is important that we better inform ourselves and contribute to discussions toward legislation that is really in the ultimate public interest.

I shall comment briefly on some of our activities.

Committee on Society Headquarters

We have not yet approached effective development of our central office organization, physically or functionally. It is my hope and expectation that we shall study the organization of other state societies and evolve a more adequate structure to meet the needs of Massachusetts, public and professional. After the present emergency has passed, some of the needs will be easier to meet. But we cannot afford to drift passively along in the meantime.

The functions of the executive secretary have greatly increased this year. He has been utilized by most of the committees, perhaps to the greatest extent by the Committee on Legislation, but this position still is not fully developed. We are growing rapidly and we must be sufficiently alert concerning present and approaching needs of organization.

The office arrangements are not satisfactory and the committee has explored the possibility of getting more space in or outside the library building. More and better arrangements for committee rooms

are needed. We have expended none of our \$1200 budget for headquarters because the committee has not been able to settle on plans.

Committee on Finance

Without the annual meeting this year, we shall not show so favorable a balance as formerly but the Society is in a sound condition financially. No other state society has lower annual dues. I think you ought to know that committee members come from the Cape to the Berkshires — for the most part at their own expense — to do your planning and organizing and to settle your problems. I am sure I spoke for the Society when I vetoed the "Dutch treat" dinners of committees while engaged in Society business.

I hold the conviction that receipts should be ploughed into service for the fellows and the people we serve.

Committee on Legislation

Dr Browne has devoted tremendous energy to the meeting of his obligations. Having myself spent many days at the legislative hearings, my perspective on the relations between doctors individually, doctors organized — the American Medical Association and the Massachusetts Medical Society — and the public has been broadened. We have been misunderstood for years. We have been admonished on numerous occasions by public administrators to come out of our temples and to let the people get to know us better. In matters of legislation, we, as the organization best informed about certain aspects of health, medical education and medical practice, *must* make our position clear to the legislators. They want to know our thought about these things. My respect for legislators has increased through a better understanding of their problems. Some of us have been inclined to forget that the public has a proper interest in fields of medical care. I think I may say that we have opposed some legislation that was supported by highly organized and well financed groups.

The Committee on Legislation has had a very busy year. There are advantages to the present organization of this committee. One member is chosen from each district society and the chairman is elected from this group, but I wonder whether a small executive committee on legislation, selected from the Society as a whole for their special capacity for contact with legislative people, might be of advantage. Contact with the legislator by his family physician could still be done by the district legislative committees.

For the Medical Society of the State of New York, Joseph Lawrence effectively developed and maintained confidence of legislators in that state for twenty-five years. He is now in Washington in a national capacity, conducting a two-way information

One cannot be exposed to public attitudes toward organized medicine at the State House without realizing the need for a better understanding of our motives and objectives.

Subcommittee on Public Information

The Committee on Public Relations has created the Subcommittee on Public Information. This committee has met with important representatives of the press and with radio, advertising and public administrators and has made a beginning this year toward a better understanding of health and distribution of medical care on the part of the public.

We have participated in radio broadcasts with dental, hospital and other groups. We have actively participated in Health Week (May 6 to 12), by radio and press contacts. We have met with the chairman of the Michigan State Society's radio committee to hear of that state's experiments in the field of public information.

There is profit in continuity of discussion of problems in distribution of medical care. Some are impatient because discussions or "conversations" do not yield immediate, definite programs. I have a conviction that unless we have these "conversations," in order to explore untried field of endeavor by group thinking, we shall not make progress toward ultimate solutions.

Subcommittee on Labor and Industry

We have made overtures toward better mutual understanding and expanding areas of agreement with labor through the Subcommittee on Labor and Industry of the Committee on Public Relations. We have also met with certain representatives of industrial management. These meetings have been frank and cordial. I am sure that they have already yielded dividends and will continue to yield profit to the groups involved, moreover, they are exercises in better citizenship.

Committee on Postwar Planning

The Committee on Postwar Planning has made substantial progress toward organizing medical schools and hospitals to meet the needs of returning medical officers. Hospital trustees have already begun to co-operate with the program. This committee is also conscious of the obligation to plan postgraduate extension so as to reach every doctor in the Commonwealth, whether or not they are members of the Society.

The Society can rest assured that its obligations in this field are in good hands. These busy men are applying themselves energetically to the solution of problems that should be actively met. Information about their activities is covered in reports to the Council.

Clinical Information Bureau

The Clinical Information Bureau is expanding its coverage of information in all branches of clinical

facilities for the benefit of every doctor in this state, regardless of whether he is a resident or a member of the Society. The service is used more and more as its value is discovered. It is planned to continue the development of this project under the wing of the Committee on Postwar Planning.

Committee on Publications

The *Journal* continues to justify our pride as one of the best in its field. I am glad to say that its editorial policy is more liberal than that of the *Journal of the American Medical Association*.

I should like to see further excursion into the coverage of news activities of the Society. This year the committees have been extremely busy and have not had reporters to summarize their activities for the proper and adequate enlightenment of the membership. I believe that the *Journal* is the proper medium for this information. We need to develop someone with reportorial instincts to see what goes on and to interpret its significance in a readable manner. Sometimes district-society publications have indicated significantly what might be done. Some policies of these local papers have, however, been contrary to my ideas of what constitutes constructive criticism. *Medical Economics* is still the best source of information and the most universally read periodical we have in this field.

Blue Shield

The Massachusetts Medical Service is the fastest growing plan of its kind in the country. We have more than 130,000 participants, twice as many as when we started the year. Our list of nonparticipating physicians has shrunk considerably. We found a great many of these were in the service or were full-time institution men. There are still some who want to see a perfect plan before they come in. It seems to me that we have the logical answer, and we shall expand as fast as experience seems to justify. There are indications now that, if the present favorable trends continue, we may be able to expand to complete hospital medical-service coverage in six months. I hope to see the local professional Blue Shield committees become more conscious of their opportunities and responsibilities.

Blue Triangle

The Blue Triangle or Bank Plan for financing costs of medical service has been initiated in this state. Because both doctors and bankers are conservative, it is expected this project will not develop like prairie fire. I am convinced that the plan is well conceived and that it fills a need that will be even more apparent after "war prosperity" has passed. The simplicity of the machinery, the low interest rates and the fact that the necessary papers are at the doctor's elbow, ensure ultimate extensive utilization of this plan by a great many

Rationing

Our central and local committees on rationing, with the assistance of the War Participation Committee, have made statesmanlike contributions toward better citizenship of doctors and patients. These excursions into the "policing" field are important and we can look with pride for the most part on our record here. We are showing that when our co-operation is sought and utilized, we earn public respect.

Tax-Supported Medical Care

This field is a large one, and it is a good deal to expect that all the coverage needed will be given by busy doctors. Veterans' medical care will soon be a tremendous problem. This is one of the fields that needs continuity of observation and contact. Perhaps a better informed headquarters staff is the only practical answer in this and some other fields.

Industrial Health

This is another field that is of increasing importance. The American Medical Association has outlined plans for county societies to implement. More energy and time is needed than has been available by specialists. Rhode Island has set us a good example. They are, of course, more highly industrialized in a concentrated area.

Health Councils

Everybody agrees that better organization of district and central health councils is needed. The Massachusetts Central Health Council has a budget of only \$200 a year. Michigan spends \$20,000 a year in this field. This kind of group activity was one of the recommendations of the Committee on the Costs of Medical Care that was endorsed by the American Medical Association. We have toyed with the idea for years, and we do not yet begin to meet our obligations.

Committee on Ethics and Discipline

This committee devotes a great many hours to conscientious and objective consideration of its problems. Because its deliberations are confidential, you hear very little about the work these men do. You can well feel confident that they strike a nice balance between idealism and realism. Defendants are treated with equal consideration regardless of professional prominence.

Committee on Membership

Some criticism has been raised toward this committee because of seeming disregard of recommendations of local membership committees. It may be that in the serious effort to maintain the highest

standards of admission, they have sometimes not given quite enough consideration to local opinion

* * *

In closing I express my deep and sincere appreciation for the loyal support that I have received. It is, more than you know, an enriching experience to be honored with leadership of this society

E S BAGNALL

MISCELLANY

DIABETES AND TUBERCULOSIS

That diabetic patients are prone to acquire tuberculosis is not a new observation, but present-day circumstances have given it a new importance. If the opportunity for effective treatment of tuberculosis is not to be lost, this sinister association must be kept in mind by the doctor. The way to safety lies in considering the possibility that tuberculosis may be now, or at any time may become, a complicating factor with every case of diabetes. The following abstract of a recent paper (Banyai, A L and Cadden, A V. Diabetes and tuberculosis. *Arch Int Med* 74:445-456, 1944) calls attention to the problem

* * *

The significance of the association of diabetes and tuberculosis is accentuated by the continued rise in the frequency of diabetes and the increase in the incidence of pulmonary tuberculosis in persons with diabetes in spite of the decline in the tuberculosis mortality rate in the general population.

Reports from American clinicians made over a period of years indicate that tuberculosis occurs four times as frequently in diabetic persons as in the general population. The age of the diabetic patient is important. One study in Massachusetts showed that tuberculosis was more than thirteen times as frequent among those who acquired diabetes before the age of fifteen as it was among a corresponding group of school children, while among adolescent diabetic patients the incidence was sixteen times as great as that in a corresponding high-school group.

Several theories have been proposed to account for the predisposition of diabetic persons to tuberculosis. Of these the one which the evidence seems to favor is that vitamin A deficiency plays a part. Since a vitamin A deficiency usually occurs in the presence of diabetes, this lack may explain in a large measure the increased susceptibility of diabetic patients to tuberculosis. Lack of vitamin A causes specific pathologic changes in the mucosa of the respiratory system which favor the invasion of bacteria into the lung and bronchial tissues.

A wide discrepancy exists between the estimated number of cases of diabetes associated with tuberculosis and the number of such patients who are admitted to tuberculosis hospitals. Failure to hospitalize these patients in specialized institutions carries serious implications relating to the welfare of the patient and to the public health. The reasons for this failure may be lack of diagnostic consciousness, improper interpretation of symptoms, incomplete diagnostic investigation and asymptomatic forms of pulmonary tuberculosis. The higher recovery rate of persons with early tuberculosis as compared with that of those with advanced tuberculosis justifies a plea for an early diagnosis of this condition in diabetic patients.

Experience has shown that the best attitude is to anticipate the possibility of tuberculosis as a complication. A tuberculin test should be given to all persons with diabetes. This test should be repeated annually as long as it is negative. For those who react positively to tuberculin there should be a chest roentgenogram every year at least. Examination of the sputum should be carried out for all patients with a productive cough and if the roentgenogram of the chest indicates reason for suspicion, fasting stomach contents should be aspirated five successive times and examined by culture or by the inoculation of guinea pigs.

The percentage of diabetic patients entering the tuberculosis hospitals with minimal tuberculosis seems to be

unduly low and may be attributed to a lack of diagnostic suspicion on the part of the physician treating the diabetes. The emphasis formerly placed on the lack of subjective symptoms of diabetic patients with active pulmonary tuberculosis is no longer valid since mass x-ray surveys have revealed that asymptomatic tuberculosis also exists among non-diabetics. Several authors have observed that cavitation is frequent when pulmonary tuberculosis is complicated by the presence of diabetes. Other complications except that of spontaneous pneumothorax occur less frequently than they do in nondiabetic patients with tuberculosis.

The management of diabetes in the presence of tuberculosis has evolved with the trend in diabetic treatment. In the authors' experience it was found that, in patients who were given a well planned diet and adequate amounts of insulin, slight glycosuria and hyperglycemia not exceeding 200 mg per 100 cc are compatible with favorable therapeutic response so far as pulmonary tuberculosis is concerned. Improvement in the pulmonary condition of patients belonging to this group compares favorably with that recorded for tuberculosis patients whose blood sugar was kept on a practically normal level.

Although it may appear heretical in the treatment of tuberculosis the authors are of the opinion that reducing the diet for overweight diabetic patients with pulmonary tuberculosis is as justifiable and practicable as for nontuberculous obese persons with diabetes. The administration of massive doses of vitamin A (150,000 to 200,000 U S P units) daily may serve as a useful adjunct in the management of diabetes mellitus complicated by pulmonary tuberculosis.

The indications and contraindications for collapse therapy are the same for diabetic as for nondiabetic tuberculous patients. Because of the frequency with which empyema complicates artificial pneumothorax in persons with predominantly exudative and caseous tuberculous lesions of recent origin, the use of this measure is rather limited for tuberculous diabetic patients.

An analysis of the reports of ten American clinicians based on the observations of 17,358 cases of diabetes indicates a higher incidence of tuberculosis in diabetic persons than in the general population of the United States.

The fact that an unusually high percentage of diabetic patients who acquire tuberculosis are not adequately treated for their pulmonary disease before it reaches the far advanced stage calls for an urgent revision of the diagnostic approach to this problem.

During the period covered by this study 115 tuberculous diabetic patients were discharged from Muirdale Sanatorium. On discharge 8 of the 17 persons with moderately advanced pulmonary tuberculosis were classified as apparently arrested, quiescent or improved, and 9 were unimproved or had died. Of the 96 persons in the far advanced group, 14 reached the stage where their disease was apparently arrested, quiescent or improved, whereas 82 patients remained unimproved or died. These therapeutic results are less favorable than those recorded for nondiabetic patients with moderately advanced and far advanced pulmonary tuberculosis. — Reprinted from *Tuberculosis Abstracts* (July, 1945)

BOOK REVIEWS

A Textbook of Pathology Pathologic anatomy in its relation to the causes, pathogenesis and clinical manifestations of disease. By Robert A Moore, M D 8°, cloth, 1338 pp., with 513 illustrations. Philadelphia and London W B Saunders Company, 1944 \$10.00

Dr Moore's new textbook of pathology is a distinctly worthwhile addition to medical literature. The book is separated into the familiar divisions of general and special pathology. A number of innovations are noted, as, for example, in the presentation of metabolic disturbances. Illustrations are numerous, well chosen and of high caliber. In addition to gross and microscopic photographs there are radiographs, clinical photographs and reproductions from manuscripts of historic importance. References are adequate in number and in most instances represent excellent selections. Preference has been given to references in the English language and to those which have appeared within the last few years. The book, therefore, may be used with value as a guide to

key papers and monographs. The correlation of physiology, chemistry and clinical medicine with pathology is emphasized throughout. The style is clear. It is perhaps too-objective and factual as though the author had tried hard to withdraw his personality completely from the lines that he has penned.

This is probably the most complete textbook of pathology written for the use of medical students. The author has apparently decided to make his book as inclusive as possible at the expense of detailed consideration of some of the more important pathologic problems. The chapter on Bright's disease and renal insufficiency, for example, contains only seventeen pages, including a historical introduction and the bibliography. Reliance is placed on tabular representation of the important clinical and pathologic features of the various types of Bright's disease as a substitute for detailed discussion.

Treatment of diseases caused by poisonous gases and by various parasites and viral agents is representative of the attempt to present a thoroughly modern textbook. A valuable addition is a brief chapter on the history and scope of pathology, with a well selected list of references for the interested student. Disagreement may be justifiable with the author's choice of emphasis and selection of material for discussion, but this is of interest only to the professional pathologist. Discussion of those diseases beyond the personal experience of the author in most instances represents adequately and fairly the best opinions in the medical literature.

On the whole Dr. Moore has written an excellent, complete and modern textbook of pathology, which should meet the requirements not only of the medical student but also of the physician who seeks brief accurate discussions of pathologic processes. The book is well printed and attractively bound.

Training Medical Secretaries in Junior Colleges. By Evangelin Markwick, Ph.D. 8°, paper, 88 pp., with 12 tables. New London, New Hampshire: Colby Junior College, 1944. No charge.

This study covers a period of nine years in which eleven junior colleges, five hundred and thirty-nine physicians from forty-five states and one hundred and twenty-four medical secretaries participated. The research was limited to training given by junior colleges. The physicians were asked to enumerate required duties in the office and in the laboratory. The medical secretaries who were trained in junior colleges were requested to enumerate various duties performed in their daily work in the office and laboratory. Sixteen comprehensive detailed tables analyze the various duties as shown by the reports of the physicians and secretaries.

An interesting part of this study has to do with working hours, salaries and the personal attributes of medical secretaries. The job specifications made by medical secretaries do not differ essentially from those made by physicians. A large majority of the secretaries, over 77 per cent, reported duties that should classify them as both office and laboratory workers. Four hundred and eighty-two physicians reported that they employed assistants for secretarial and laboratory work. Two hundred and twenty-five of the three hundred and fifty physicians reporting on laboratory training for medical secretaries believe that the duties could be taught in a college laboratory.

This study indicates that a significant proportion of physicians need medical secretaries and believe that colleges with well equipped and properly staffed laboratories could prepare them adequately.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

An Outline of Tropical Medicine. By Otto Saphir, M.D., director, Department of Pathology, Michael Reese Hospital, and professor of pathology, University of Illinois College of Medicine. 12°, cloth, 86 pp. Chicago: The Michael Reese Research Foundation, 1944. \$1.00.

This small manual has been written for physicians who may be brought into contact with tropical diseases under

present conditions. The outline summarizes the barest essentials of the more important tropical diseases. Diseases due to fungi, to vitamin deficiencies and to snake and insect poisonings are not included. Only brief mention is made of diseases caused by animal parasites. Diseases occasionally encountered in the United States, such as amebic and bacillary dysentery, commonly described in any textbook, are omitted. It is hoped that this small volume will serve as a ready reference manual for the general practitioner.

Handbook of Diagnosis and Treatment of Venereal Diseases. By A. E. W. McLachlan, M.B., Ch.B. (Edin.), D.P.H., F.R.S. Ed., clinical medical officer, Joint Committee's Clinic, medical officer-in-charge, Venereal Diseases, Newcastle General Hospital, and lecturer in venereal diseases, King's College, University of Durham. 12°, cloth, 364 pp., with 159 illustrations. Baltimore: Williams and Wilkins Company, 1944. \$5.00.

The British regulations of 1916 define venereal diseases as syphilis, soft sore and gonorrhea. This manual has been evolved from the clinical and systematic instruction of under-graduate and postgraduate students over a period of years. It is written for the general practitioner, and emphasis is placed on the importance of early diagnosis. The book is well printed on good paper with a good readable type.

Escleroses Valvulares Calcificadas. Estudo anatomo-patológico, radiológico e clínico com apresentação de cem casos. By Roberto Menezes de Oliveira, M.D., member, Corpo Médico da Aeronáutica, Brazil. 8°, paper, 154 pp., with 67 illustrations. Rio de Janeiro: Tipografia do Patronato, 1943.

This special monograph on valvular calcification is divided into five parts and a summary. The first part discusses the anatomy and histology of the cardiac valves, the second, the pathological anatomy of calcification, the third, radiography of the diseased heart, the fourth, clinical aspects of the disease, and the fifth, the clinical histories of a hundred cases diagnosed roentgenologically. There is also included the pathological and anatomical study of twenty-five autopsied cases. Appended to the text is a bibliography of twenty-six references, and the work concludes with a summary in English.

Familial Susceptibility to Tuberculosis. Its importance as a public-health problem. By Ruth R. Puffer, Dr. P.H., Tennessee Department of Public Health. 8°, cloth, 106 pp., with 9 figures and 21 tables. Cambridge: Harvard University Press, 1944. \$2.00.

Since 1931 the International Health Division of the Rockefeller Foundation has sponsored the study of tuberculosis in Williamson County, Tennessee. The material collected during this survey has been analyzed by Dr. Puffer in this monograph.

P-Q-R-S-T. A guide to the interpretation of electrocardiograms. By Joseph E. F. Riseman, M.D., associate in medicine, Harvard Medical School, instructor in medicine, Tufts College Medical School, and associate in medical research and associate visiting physician, Beth Israel Hospital, Boston. 24°, cloth, 28 pp., illustrated. Cambridge: Sanborn Company, 1944. \$1.50 (plus postage).

This small booklet is intended for use by the beginner as a practical guide during the actual examination and interpretation of electrocardiographic tracings. It is illustrated with fifty-five tracings.

Outline of the Amino Acids and Proteins. Edited by Melville Sahyun, M.A., Ph.D., vice-president and director of research, Frederick Stearns and Company, Detroit. 8°, cloth, 251 pp., illustrated. New York: Reinhold Publishing Corporation, 1944. \$4.00.

This joint manual written by fourteen chemists outlines in a simple and readable manner the essentials of the chemistry and the biochemistry of amino acids and proteins. An attempt has been made to present a clear and accurate picture of this difficult subject. The authors have refrained from entering into the theoretical controversial aspects of the various theories dealing with the proteins.

SPLENECTOMY FOR ACQUIRED HEMOLYTIC JAUNDICE IN THE AGED*

Report of a Case

DAVID F JAMES, M D,† AND LLOYD R EVANS, M D †

BOSTON

A PATIENT who develops severe hemolytic anemia at the age of seventy and has no past history of this disease presents complex problems in diagnosis and treatment. The age of onset is late for the diagnosis of congenital hemolytic jaundice and, regardless of the diagnosis, the question arises whether splenectomy is advisable at this age. Furthermore, increased fragility of the erythrocytes may be overlooked when the routine test for fragility is done on blood samples showing marked anemia. These problems were met in a seventy-year-old woman in whom splenectomy was performed with recovery. The literature was reviewed to determine the usefulness of splenectomy in the treatment of acquired hemolytic jaundice in patients with the onset of the disease occurring after the age of fifty.

CASE REPORT

M E F, a 70-year-old, married woman, was admitted to the Peter Bent Brigham Hospital for the first time on April 15, 1941. The chief complaint was weakness of 3 to 4 months' duration. The family history revealed no case of anemia, jaundice or endocrine disorders, the mother and only brother had suffered from heart disease. The patient had lived in New England all her life, had never been pregnant and gave no history of exposure to any materials known to be injurious to the blood or blood-forming tissue. Systemic review disclosed that the patient's health had always been good in the past.

Four months prior to admission the patient first experienced malaise, increased weakness, fatigability, palpitation and shortness of breath on exertion. She did not complain of paresthesias and gave no evidence to suggest blood loss, bleeding dyscrasia or liver disease. A month later she consulted a physician on account of these complaints. Not until 2 weeks before admission did the skin assume a yellow tint and her physician discover a low red-cell count. Bed rest and the administration of liver extract by mouth during 2 weeks brought no improvement.

On admission the patient appeared to be severely ill, as evidenced by prostration, tachycardia, pallor and a lemon-yellow skin. The tongue was smooth and pale. There was a palpable lymph node in the left supraclavicular region. The blood pressure was 130/40. The heart was slightly enlarged to the left, and there was present a loud blowing systolic murmur, heard best over the cardiac apex. The liver extended 2 cm below the right costal margin, and the spleen was barely palpable. Neurologic examination revealed no abnormalities.

Significant laboratory data included negative Wassermann and Hinton blood tests. The urine was normal except for a + test for protein. The red-cell count was 870,000, with 17 per cent reticulocytes. The white-cell count was 17,500, with 75 per cent neutrophils, 19 per cent lymphocytes, 4 per cent monocytes and 2 per cent unidentified cells, 2 normoblasts were found among 100 leukocytes. The hemoglobin was 32 per cent (Sahli). The icteric index was 20, and by the Sanford¹ method of erythrocyte fragility determination, hemolysis began at 0.44 per cent saline solution and was complete at 0.42 per cent, a normal result by the method used.

When correction was made for the anemia,² the initial hemolysis was found to occur at 0.58 per cent saline solution, whereas a normal control showed the same amount of hemolysis in a 0.44 per cent solution. There was 75 per cent hemolysis in 0.40 per cent saline in the blood, the same degree of hemolysis occurred at 0.35 per cent saline in the blood of the normal control. In addition, the patient's blood gave a negative hemolysis test with acidified serum³ and contained no hemolysins of the Donath-Landsteiner type, no auto-hemolysins and no agglutinins in the presence of cold or heat. Plasma hemoglobin amounted to less than 7 mg per 100 cc, and was considered normal. At that time (3 weeks after admission) the red-cell count was 1,200,000, with 4.9 gm of hemoglobin per 100 cc, and 29 per cent reticulocytes. The hematocrit reading was 16.6, the mean corpuscular volume 138.3 cubic microns, the mean corpuscular hemoglobin concentration 30 per cent, and the mean corpuscular hemoglobin 42 micromicrogm. The white-cell count was 13,600 with 54 per cent segmented neutrophils, 13 per cent band forms, 4 per cent eosinophils, 21 per cent small lymphocytes, 4 per cent large lymphocytes, 3 per cent adult monocytes and 1 per cent young monocytes. A smear showed moderate anisocytosis, macrocytes and normocytes were seen. There was much polychromatophilia, with some Howell-Jolly bodies, stippling and a few erythroblasts and normoblasts. No spherocytes were seen. The platelets and white cells were normal. A direct van den Bergh test showed 0.9 mg of bilirubin per 100 cc of plasma and an indirect one 3.1 mg §. Roentgen-ray films of the chest, gastrointestinal tract, skull and long bones failed to disclose disease. Gastric aspiration revealed free hydrochloric acid to the extent of 22 units in the sample withdrawn 20 minutes after histamine injection.

Following the injection of six doses, totaling 8 cc, of liver extract (Lederle, N N R) and a transfusion of 500 cc. of whole blood, the red-cell count was only 1,430,000, with no increase in reticulocytes. The hematocrit reading was 19, and the icteric index 30. The patient felt improved and was discharged home on May 13, approximately 1 month after admission.

After spending a week at home the patient became so chronically exhausted that she was readmitted. Physical examination at that time was essentially the same as before. The red-cell count was 1,020,000, the hemoglobin 3.75 gm per 100 cc, the hematocrit 12, and the icteric index 18. The white-cell count was 33,100, with a normal differential ex-

†Formerly medical house officer, Peter Bent Brigham Hospital.

§The determinations listed were made by Dr. Henry H. Brewster and Miss Geneva A. Daland of the Thorndike Memorial Laboratory, Boston City Hospital.

cept for 4 per cent normoblasts and 1 per cent megaloblasts. The fragility of the erythrocytes was again studied. By the method of Sanford, hemolysis began at 0.44 per cent saline solution and was complete at 0.34 per cent, both values being within the limits of normal and equivalent to those of a normal control blood tested at the same time. When, however, enough plasma had been removed from the blood of the patient to make the hematocrit reading normal—that is, 40—and the fragility was again tested by the Sanford method, it began at 0.50 per cent and was complete at 0.40 per cent, values definitely indicative of greater fragility than normal. In order to check the findings of these naked-eye tests, the photoelectric method of Hunter⁴ was used, testing blood with a hematocrit level of 17. When fragility was determined by this method, hemolysis began at 0.60 per cent saline and was complete at 0.36 per cent, whereas in the normal control it began at 0.48 per cent and was complete at 0.34 per cent.

During this stay roentgen-ray therapy—two doses of 25r each directed at the entire trunk on successive days—was administered on the supposition that the etiologic process might be neoplastic in nature, and was followed by a fall in the white-cell count from 25,000 to 11,000 and a decrease in reticulocytes from 18 to 6 per cent. It was therefore discontinued. Twelve days and 29 days later the reticulocytes numbered 6 per cent and 9 per cent, respectively.

On June 8, 3 weeks after admission, the patient experienced an attack of severe pain in the right upper quadrant of the abdomen. A mass in the right upper quadrant, corresponding to the gall bladder, became palpable and remained so for 24 hours, after which it could no longer be felt. The findings were interpreted as indicative of obstruction of the cystic duct. Biopsy of the palpable left supraclavicular lymph node revealed tuberculous lymphadenitis. On the 24th day, a biopsy of the sternal bone marrow was performed and was interpreted as showing hyperplasia of the marrow, chiefly erythroblastic in nature, and probably secondary in origin.

Because of the above findings and the failure of the patient to improve on vigorous transfusion therapy,—she received a total of 7600 cc of whole blood in 1 month,—she was transferred to the Surgical Service for splenectomy. On June 29, the day of her transfer, the red-cell count was elevated to 2,100,000 by repeated transfusions. The following day splenectomy was performed, the patient withstanding the procedure well. She received two more transfusions on the day of operation. On the first postoperative day the red-cell count was 2,600,000. No further transfusions were given.

At operation the gall bladder was seen to be tense and distended. It did not empty on pressure, no stones could be palpated. It was not removed. The liver did not appear abnormal to inspection or palpation. The weight of the spleen was 362 gm. Following is the report on the pathological examination of the spleen.

The color of the cut surface is dark red. The malpighian bodies are not prominent. There is no grossly evident increased trabeculation. No areas of infarction are encountered. Microscopical examination discloses that the capsule is not remarkable. The malpighian corpuscles are essentially normal in color and size. They are quite active, with sometimes moderately prominent germinative centers. The reticular cords, however, show definite lymphoid depletion, and there is a certain degree of engorgement of the meshes of the red pulp. One of the most striking features is the presence of large amounts of golden-brown pigment consistent with hemosiderin. This is found extracellularly as well as intracellularly. In the latter instance it is within large monocytes, or often within the lining cells of the sinuses. Scattered through the organ there appear to be a somewhat increased number of polymorphonuclear leukocytes. Another striking feature is the presence of foci of hematopoiesis mostly situated near the malpighian corpuscles, and there is also hematopoiesis going on within the sinuses. The number of eosinophilic myelocytes is quite excessive, and occasional megakaryocytes are encountered. The general architecture is well preserved. The sinuses are frequently prominent. The large arteries show only a minimal degree of sclerotic changes, whereas the small arterioles are rather uninvolved. This picture of marked hematopoiesis

with extensive hemosiderin deposits is quite consistent with that of a hemolytic anemia.

After an uneventful postoperative course of 11 days, the patient was transferred to the Medical Service, at which time the red-cell count was 3,500,000. She appeared much stronger and happier than at any previous time during the hospital stay. When she was discharged on the 22nd postoperative day, she was ambulatory and the red-cell count was 4,300,000, with 11.5 gm of hemoglobin per 100 cc, 26 per cent reticulocytes and an icteric index of 14.

The patient was seen again 4 months after splenectomy, at which time she looked well and had regained her strength so that she was able to arise at 5.30 every morning. No pallor or jaundice could be detected. The red-cell count was 4,560,000, with 13.5 gm of hemoglobin per 100 cc. The white-cell count was 8400, with 36 per cent segmented neutrophils, 1 per cent band forms, 52 per cent lymphocytes, 8 per cent monocytes and 3 per cent eosinophils. There were 0.5 per cent reticulocytes. Platelets were plentiful, and the blood smear appeared normal except for the variations in red-cell size described below. No spherocytes were seen.

Fragility tests done by the photoelectric method of Hunter disclosed that the red cells were still definitely more fragile than those of a normal control. In 0.60 per cent saline solution 5.4 per cent of the erythrocytes were hemolyzed, whereas hemolysis did not begin in the control blood until the hypotonicity of the salt solution had reached 0.51 per cent. Ninety-eight per cent of the cells were hemolyzed at 0.36 per cent saline, whereas but 87.5 per cent hemolysis occurred in the blood of the control at this concentration. Fragility tests performed on the blood of the patient's sister and grandnephew, the only relatives available, failed to reveal aberrations from the normal.

A Price-Jones curve showed a range of red-cell diameters considerably wider than normal. Of 500 erythrocytes examined, one had a diameter of 3.1 microns, one of 3.5, one of 3.9, and 22 of 4.2. The peak of the curve occurred at 7.0 microns. There were 11 cells with a diameter of 9.1 microns, and 4 with a diameter of 9.8. Price-Jones curves done on the blood of the patient's sister and grandnephew failed to reveal abnormalities.

On March 16, 1942, over 8 months after splenectomy, the patient reported that she was entirely well and more vigorous than she had been at any time in the previous 10 years.

DISCUSSION

This case yields information on three phases of the diagnosis and treatment of hemolytic jaundice. First, the disparity among results obtained with various types of erythrocyte fragility tests deserves comment. Second, an attempt to classify the patient's anemia as either the congenital or the acquired form helps to evaluate recent studies of certain features of these syndromes. Third, the patient's advanced age at the time of onset and of splenectomy is of interest, since only 1 other case of splenectomy for hemolytic jaundice in a patient over seventy years of age has been found in the literature.⁵

Estimation of Erythrocyte Fragility

The Sanford red-cell fragility test, although widely used and usually adequate for the detection of gross changes, gave an erroneous result in this case in the presence of marked anemia. Although a large percentage of the red cells were abnormally fragile, the anemia was so marked that the quantity of blood used in the test did not contain enough such

is to produce hemolysis detectable to the eye. When, however, the anemia was corrected by removing sufficient plasma to bring the packed red-cell volume to a normal level, the abnormal fragility of the cells was immediately apparent.

In anemic cases it is not necessary to bring the red-cell volume to normal before determining the fragility of the erythrocytes if the method used in estimating the percentage of the cells hemolyzed by the various concentrations of saline solution is sufficiently accurate. The fragility test as adapted by Hunter⁴ to the photoelectric colorimeter meets this requirement. A minor modification of this method was made to save time. Constant and reliable values could be obtained by mixing the various dilutions of saline solution with blood in Klett-Summerson colorimeter tubes, centrifuging at 3000 r p m for twenty minutes and measuring directly the amounts of hemoglobin in these tubes without decanting the supernatant into other tubes. No ammonium hydroxide was added.

Diagnosis of Congenital and Acquired Hemolytic Jaundice

The natural history of classic congenital hemolytic jaundice is well known. Typically there are episodes of anemia, acholuric jaundice, notable splenic enlargement and upper-abdominal pain from cholelithiasis. Whereas the symptoms tend to appear and disappear, the following signs persist throughout microspherocytosis with increased fragility of the erythrocytes in hypotonic saline solutions, accompanied by anemia, reticulocytosis and increased urobilinogen content of feces. The disease frequently manifests itself in childhood or early adulthood, but may never be detected. Although the past history and family history may not reveal the presence of any of these features, blood studies of relatives of patients with this disease frequently demonstrate increased fragility, which is inherited as a mendelian dominant.⁶ Many cases remain entirely asymptomatic throughout life, a few develop in older age groups. This work indicates that a case of hemolytic jaundice should not be termed congenital until evidence is found in the family of characteristic symptomatology or of microspherocytosis or increased red-cell fragility. The discovery of any or all of these characteristics in the blood is not enough to make the diagnosis certain. Meulengracht, cited by Dameshek and Schwartz,⁷ denied that increased saline fragility was pathognomonic of congenital icterus, and reported cases of the acquired type with increased fragility. Furthermore, he stated that an inherited disturbance in formation was only one of the causes of increased fragility of the erythrocytes, and that actually the increase might be regarded as a regeneration phenomenon or as a sign of the action of toxic or hemolytic forces on the red cells in the circulation. Ham and Castle⁸ comment on the

effect of erythrostatics in the spleen and other organs to increase erythrocyte fragility in presumably otherwise normal persons. They report on the transient but striking increase in fragility that occurred in 5 cases of severe acute hemolytic anemia observed following the administration of sulfanilamide. This was so great that some of the red cells in venous samples were hemolyzed in isotonic or only slightly hypotonic saline solution. These authors believe that erythrostatics occurring in the spleen and other organs was "presumably operative" in bringing about the increased fragility. Watson⁹ refers to 2 cases classified as macrocytic hemolytic anemia in association with liver disease that exhibited decreased resistance of the erythrocytes to hypotonic saline solution, without spherocytosis. These data demonstrate the difficulty in determining the fundamental nature of a hemolytic jaundice from fragility studies alone.

Singer and Dameshek¹⁰ report a series of cases of so-called "symptomatic" hemolytic anemia, occurring in conjunction with other diseases (dermoid cyst in the ovary, chronic lymphatic leukemia, Hodgkin's disease, lymphosarcoma, severe liver disease and pneumonia with a panagglutinin). In these cases spherocytosis and increased hypotonic saline-solution fragility were frequently present. In the case associated with dermoid cyst in the ovary, splenectomy had a transient effect on the hemolytic jaundice, but removal of the tumor itself was marked by general improvement, subsidence of spherocytosis and a return of erythrocyte fragility to normal. Haden¹¹ also states that spherocytosis may occur in hemolytic anemia other than congenital hemolytic jaundice, reporting that it may be the result of leukemia, Hodgkin's disease or acetylphenylhydrazine poisoning. All these data indicate that a diagnosis of congenital hemolytic jaundice may not be made solely on the basis of laboratory findings in the blood of the patient.

In the case described we were not able to make a diagnosis, either preoperatively or postoperatively, of hemolytic jaundice of proved congenital origin. The most cogent points that argued against the congenital type were three in number. First, the history was not typical of the congenital form, with the sudden appearance of severe hemolytic anemia in old age. Second, there was no history among the patient's relatives of any condition resembling hemolytic jaundice, and the available relatives gave no laboratory evidence of the hematologic characteristics of this disease. Finally, the microscopic examination of the spleen was not characteristic of congenital hemolytic jaundice.¹² The pulp was only moderately filled with erythrocytes, the malpighian corpuscles were not obscured, and there was present an abnormal degree of phagocytosis. Therefore, the diagnosis made was relatively acute hemolytic anemia of the acquired variety. Since this diagnosis was made by exclusion, we cannot be certain that

our case was of the acquired variety any more than a disease can be called "acquired" unless a definite etiology can be established. It is concluded, however, on the basis of the data outlined above that the probability of its being acquired is great.

Acquired hemolytic anemia represents a heterogeneous group of cases, and may be broken down, for purposes of classification and therapy, into two subdivisions: those of known etiology and those whose etiology is unknown. Among the known causes are poisoning with such drugs as sulfan-

have no remedial effect on this patient's acquired hemolytic jaundice, made it seem advisable to try all other reasonable therapeutic measures first. Intensive liver and iron therapy, intensive transfusion therapy (which was marked by an increasing frequency of reactions) and roentgen-ray therapy directed at the trunk, however, were ineffective or of no permanent benefit. Splenectomy, on the other hand, proved effective.

Subsequent study of the literature revealed 15 patients, including the one here reported, in whom

TABLE 1 *Splenectomy Resulting in Definite Improvement*

CASE No	SOURCE	AGE AT ONSET	RED-CELL FRAGILITY	SPHEROCYTOSIS	RESULTS OF SPLENECTOMY	PATHOLOGICAL REPORT ON SPLEEN
1	Mandelbaum ⁵	75	Normal at onset, later increased preoperatively and postoperatively	Present	Slow but steady improvement	Weight, 650 gm., thickened trabeculae, reticuloendothelial elements increased, sinuses distended and lining cells prominent; much extracellular and intracellular iron-containing pigment.
2	Israels and Wilkinson ¹³ (Case 2)	57	Increased	Present	Slow but steady improvement	Weight, 700 gm., no increase in connective tissue; sinuses dilated, histiocytes remarkably prominent in pulp; erythrocytes very scanty.
3	Davidson and Fullerton ¹⁴ (Case 6)	60	Normal	Absent	Good recovery during bronchitis 4 years later; the patient was mildly jaundiced.	Malpighian corpuscles smaller than usual and widely separated owing to an increase in pulp, which was due to an excessive number of red cells; findings consistent with usual findings in acholuric jaundice.
4	East ¹⁵	52	Normal preoperatively; slightly increased postoperatively	Not mentioned	Slow but steady improvement	Weight, 600 gm., normal malpighian corpuscles, hyperplastic endothelium, whose cells contained large iron-bearing granules, phagocytosis of red cells and occasional giant cells.
5	James and Evans	70	Normal by ordinary methods; increased if corrected for anemia, preoperatively and postoperatively	Absent	Good recovery	Weight 362 gm.; marked hematopoiesis with extensive hemosiderin deposits both within and without cells; normal malpighian corpuscles.

ilamide,⁸ acetylphenylhydrazine¹¹ and others. Also, this syndrome may occur in conjunction with other diseases, notably lymphomatous neoplasia.^{10, 11} Still other cases occur without any pathologic accompaniment. As has been stressed above, increased erythrocyte fragility and microspherocytosis may be found in any of these types of acquired hemolytic jaundice, although less constantly than in the congenital form.

Splenectomy for Acquired Hemolytic Jaundice in the Aged

Splenectomy is attended by greatly increased risk when performed, for whatever reason, on aged persons.⁷ This fact, together with the distinct possibility that the removal of the spleen might well

the onset of hemolytic jaundice occurred at or beyond the age of fifty, and in whom not all the essential criteria for a diagnosis of congenital hemolytic jaundice, as discussed above, were present. About half these were patients in their fifties. Two had passed their seventieth birthday at the time of onset, the patient here described being seventy and another being seventy-five. The family and past histories were noncontributory. Symptoms and physical signs — which were of no differential diagnostic or prognostic import — included loss of energy, anorexia, weakness, palpitation, shortness of breath on exertion, pallor, jaundice and enlargement of the liver and, somewhat more regularly, of the spleen.

Of the 15 cases, 5 showed definite improvement

ter splenectomy These 5 cases comprised the 2
er seventy years of age, 1 in the sixties and 2 in
the fifties The essential data are summarized in
Table 1 It is interesting to note that in only 1 of
these cases (Case 3) was there a pathologic picture
like that seen in congenital hemolytic jaundice In
this case fragility of the red cells was said to be nor-
mal, and spherocytosis was not mentioned In the
other spleens a marked increase in the number and
activity of reticuloendothelial elements was found
In 10 of the cases reported in the literature
splenectomy was ineffective or resulted in accelera-
tion of the downhill course Of these, 6 are sum-
marized in sufficient detail to make an analysis
valuable (Table 2) It will be noted that in but 1

erythrocyte fragility have a better prognosis than
do those with normal fragility In the group of 5
cases showing improvement after splenectomy, 2
showed increased fragility preoperatively In 2
others the fragility, although reported as normal
before operation, increased after recovery It
is probable that in the studies made before operation
the presence of anemia masked the increased fragility
of the erythrocytes In the group of 6 cases
analyzed in which splenectomy failed to result in
improvement, 3 showed increased erythrocyte
fragility It is impossible to say how many more
of these might have manifested increased fragility
had more accurate methods been used

The cases reviewed from the literature, as well as

TABLE 2 *Splenectomy Without Improvement*

CASE No	SOURCE	AGE AT ONSET	RED-CELL FRAGILITY*	RESULTS OF SPLENECTOMY	PATHOLOGICAL REPORT ON SPLEEN
1	Watson ⁹ (Case 74)	67	Increased	Atelectasis and death on 3rd postopera- tive day	Weight, 880 gm sinuses markedly dilated †
2	Davidson and Fullerton ¹⁴ (Case 9)	51	Normal	Blood count pro- gressively decreased with death 10 days postoperatively	Weight 815 gm. marked prolifera- tion and activity of reticuloendo- thelial system definite myeloid metaplasia findings said to be "typical of reticuloendotheliosis"
3	Thompson ¹⁶ (Case 33)	63	Normal	Death 6 wk. postopera- tively autopsy no aid in diagnosis	Weight, 680 gm evidence of marked blood formation
4	Davidson ¹⁷ (Case 5)	55	Normal	Reticulocytosis persist- ed death 10 mo later of anemia	Weight 1700 gm histiocyte pro- liferation and myeloid metaplasia characteristics of congenital hemo- lytic jaundice absent.
5	Davidson ¹⁷ (Case 9)	58	Increased	Congestive heart failure 36 hr. postopera- tively red-cell count 470 000 at time of death	Weight 820 gm pulp contained in- numerable red cells without marked dilatation of sinuses the appearances were said to be "those of acholuric jaundice."
6	Rastetter and Murphy ¹⁸ (Case 2)	53	Slightly increased	Icterus anemia and re- ticulocytosis re- turned after 1 mo improvement death 2 wk. later	Weight 560 gm section showed dark red pulp with faintly visible follicles marked congestion of sinuses reticulum cells scant.

*No spherocytes were found in any of the cases listed in this table.

†This patient also had hepatic cirrhosis

of these cases (Case 5) did the spleen show a micro-
scopic picture like that of congenital hemolytic
jaundice. This patient died of obvious congestive
heart failure thirty-six hours postoperatively It is
probable that there was not time for the effect of
splenectomy to be demonstrated The remaining
4 cases, which are not included in Table 2, were
reported by Dameshek and Schwartz⁷ and are those
of acute acquired hemolytic anemia in all of which
operative death occurred The ages in these cases
ranged from fifty to sixty-four

In 6 of these 10 cases, the primary cause of death
was found to be closely related to the operative
procedure, whereas in 3 the blood dyscrasia itself
was the principal lethal agent One patient died six
weeks after operation, and autopsy did not help to
make a diagnosis Presumably this death also was
related to the hemolytic process

The question arises whether cases with increased

the one reported here, demonstrate that splene-
ctomy may save the lives of elderly patients with
acquired hemolytic jaundice, and that it should not
be regarded as a useless procedure Although good
results following splenectomy are likelier in a patient
with increased erythrocyte fragility, spherocytosis
and a spleen typical of congenital hemolytic jaun-
dice than they are in others, it is sometimes of value
in patients whose clinical picture lacks one or more
of these characteristics

SUMMARY

A case of severe acquired hemolytic jaundice with
onset at the age of seventy, apparently cured by
splenectomy, is presented

The technic of determination of erythrocyte
fragility is discussed The shortcomings of widely
used methods are pointed out, and the advantages

of recent improvements devised by various workers are described

The differential diagnosis of hemolytic jaundice is discussed, with special reference to the diagnostic import of abnormally fragile red cells and of microspherocytosis

From the literature are reported 14 other cases of acquired hemolytic jaundice, with onset after the age of fifty in which splenectomy was performed. Factors influencing the course of these cases are presented

THE DEVELOPMENT OF THE STATE CHILD-GUIDANCE CLINICS IN MASSACHUSETTS*

EDGAR C YERBURY, M D,† AND NANCY NEWELL, Ed M ‡

BOSTON

THE Commonwealth of Massachusetts was the first state to provide by legislation (in 1922) for a division of mental hygiene,¹ with the establishment of child-guidance clinics financed by state funds as one of its major activities. A review of the diversely related developments in psychiatric therapy that culminated in the child-guidance movement shows the state guidance clinics emerging at the peak of the mental-hygiene movement as the logical but unforeseen outcome of efforts to promote mental health by preventive and early correctional treatment.

The mental-hygiene movement expanded with remarkable rapidity through the years 1912 to 1922 under the impact of new psychiatric concepts of mental disease and an increasing revelation of the importance of flaws of personality in precipitating breakdowns in adult life.

A concurrent stimulus was contributed through the adoption by mental hospitals of social services, which brought to light many pertinent aspects of life experiences of patients by means of investigations in the homes and collaboration with local agencies. This type of social service rapidly developed into a specialized profession forming a connecting link be-

tween the hospitals and the communities that they served, and providing a valuable medium for the interpretation of the principles of mental hygiene to the lay public. By 1922, Massachusetts was considered a leader in the new field of psychiatric social service, and trained workers were in great demand by other states.² This expansion of community services was facilitated by the establishment of outpatient clinics for supervision of released patients. These clinics soon became centers for treatment of noncommittable patients, among whom were some children, chiefly delinquents.

In 1919, the General Court of Massachusetts made obligatory the examination of all school children who were three-years retarded, and the formation of special classes where ten or more such children were found.³ The examining service was provided by the state hospitals and the Walter E. Fernald State School (for the feeble-minded) by means of clinics distributed through the Commonwealth and called "traveling school clinics." The impetus that this procedure gave in the direction of child guidance was incalculable and proved to be a most notable contribution to the program of mental hygiene. Although the service was at first viewed by school boards with suspicion and fear of increased expense for special classes, it quickly demonstrated its value, and schools began to refer

†Formerly director of the Division of Mental Hygiene, Massachusetts Department of Mental Health.

‡Research social worker, Division of Mental Hygiene, Massachusetts Department of Mental Health.

many children whose difficulties proved to be due not to mental deficiency but to physical or environmental handicaps

By 1920, in addition to the traveling school clinics, a number of outpatient mental-hygiene clinics were well established, giving service to adults and children. Northampton had four clinics, and Gardner three. In 1921, Monson had four, Danvers seven, and Taunton two, and Worcester had opened such a clinic at the Summer Street Department.⁴ At that time, the Boston Psychopathic Hospital was established as an independent unit for screening of committable cases and furnishing treatment for milder forms of mental illness. The latter service was in immediate demand and was faced with problems from infancy to adulthood.⁵

By acts of 1921 and 1924, the Division for the Examination of Prisoners was established and financed by the Commonwealth, and was completely equipped with psychiatric and social services.

The case histories in all these different fields presented striking similarities of etiologic factors and unmistakable indications that the most fertile field for mental hygiene lay in the realm of childhood. Meanwhile sporadic experiments in specialized clinics for children were being made throughout the country, chiefly directed toward the treatment of delinquency. In 1922, a series of demonstration clinics was planned by the National Committee for Mental Hygiene through its Division for the Prevention of Delinquency. This was financed by the Commonwealth Fund on a five-year plan, and the clinics were located in eight specially selected cities. Of these eight clinics, four survived the exigencies of pioneering, another was subsequently resuscitated, and another was reorganized by two communities, resulting in seven established clinics. The chief problem was the continued financing after termination of the demonstration period. Results of therapy with adjudged delinquents were discouraging, but again the signposts pointed toward earlier recognition and treatment of maladjusted children.⁶

In this preliminary period, prior to 1922, one phase of clinical procedure was worked out that has remained standard to date, namely, the professional clinic team of psychiatrist, psychologist and psychiatric social worker. Although many variations of responsibility have been used, in actual practice each has been found to have its indispensable contribution toward the evaluation and treatment of cases, and the combination has proved more effective than the efforts of any one type of worker.

In Boston, in November, 1921, Dr. Douglas A. Thom was asked to make a survey of one of the health clinics of the Baby Hygiene Association of Boston to determine whether a psychiatrist might have something to contribute to the clinics' program of preventive medicine.⁷ From misgivings concerning the possibility of accomplishing anything with

these immature patients, Dr. Thom was quickly converted to enthusiasm for the rich field of opportunity that opened before him.⁸ Soon three clinics for young children were put in operation under his direction by the Community Health Association (visiting nurses), and were called "habit clinics" as an innocuous but descriptive name. These seemed to be the first clinics in the country that were established specifically for psychiatric therapy for young children.⁹ With startling clearness, the social evils of poverty, disease, ignorance and vice came into focus as the ravagers of childhood and the breeding ground of mental disease.

In 1922, Dr. George M. Kline, with Dr. Thom and other leading psychiatrists, spurred on by the ominous crowding of the state hospitals, presented to the Legislature a preventive program and secured the establishment of the Division of Mental Hygiene, under the Department of Mental Health, with Dr. Thom as director. The division was charged with the responsibility for "all matters affecting the mental health of citizens of the Commonwealth, investigation of causes and conditions that tend to jeopardize mental health."¹⁰ State funds were appropriated for research and for children's clinics.

In 1923, three clinics* were opened in Boston, by the Division of Mental Hygiene and were promptly utilized by children's agencies, visiting nurses and family-welfare workers. In this year also, the Worcester State Hospital established a habit clinic for children such as had previously been seen at its Psychiatric Clinic.¹¹ This clinic was later discontinued and the children were seen at the Memorial Hospital.¹² In 1924, four additional clinics were started by the division.[†] The clinic in the West End (Boston) is still flourishing, having given twenty years of service to a wide area. Two years later the Lynn Clinic was transferred to the auspices of the Danvers State Hospital in order that the clinic staff of the division might be available for a new clinic at Quincy. The Springfield Clinic, which was started as a demonstration clinic because of its distance from Boston, was assisted by private agencies after one year of operation and received general supervision from the Monson State Hospital.[‡]

The initial work of projecting clinics in new communities was undertaken jointly by the division and the Massachusetts Society for Mental Hygiene,¹⁴ which has carried on an aggressive and effective program since the beginning of the movement.

*The first of these was established on June 6 at the Maverick Dispensary, East Boston. It was transferred to the auspices of the Boston Psychopathic Hospital on July 2, 1924. The second was begun on June 8, 1923 at the North End (Boston) Health Unit. It was closed in July, 1928 and reopened in October, 1928, at the North Bennet Street Industrial School. It was consolidated with the West End Clinic in October, 1929. The third was established on October 25, 1923 at the Roxbury Neighborhood House and was closed on September 18, 1924.

†The first was opened on January 12, 1924 at the West End Health Unit, West End (Boston) the second on March 5, 1924 at the Lynn General Hospital (transferred to the Danvers State Hospital on March 30, 1926) the third on April 25, 1924, at the Lawrence General Hospital (transferred to the Danvers State Hospital on March 5, 1940) and the fourth on October 24, 1924 at Springfield (transferred to the supervision of the Monson State Hospital on October 31, 1925 and reorganized with community support on November 20, 1938).

Opportunities were sought for talks and conferences, and when sufficient interest was aroused a sponsoring group was organized to promote publicity, find accommodations and consult with the clinic team on community problems. Theoretically, all the clinics set up by the division were for demonstration, and were eventually to be turned over to hospitals or private organizations. This plan has been carried out except in communities easily available from Boston.

In 1925, four more clinics were in operation.* The clinic at the Boston Dispensary became a part of the Children's Department of this hospital, and in 1933 service was extended to two sessions weekly and the clinic provided training in child therapy for medical interns. The Lowell Clinic also started in a local general hospital, but after two years gave over its patients to a private clinic in the community. Four years later, at the request of schools and agencies, it was reopened and has continued service to date. The Reading Clinic was opened as a monthly diagnostic service for the school department, and in 1931 service was extended to weekly sessions for child guidance and treatment. After a period of full activity conditions changed, and it was closed in 1939 because of decreasing community interest and pressing demands for service by the City of Brockton. The Beverly Clinic also gave diagnostic service until 1931, when it became well established as a weekly guidance clinic. It was taken over by the Danvers State Hospital in 1932.

The Out-Patient Department of the Worcester State Hospital was reorganized during 1925¹⁵ to provide more specialized treatment for children attending the Psychiatric Clinic at the Memorial Hospital.

Already various patterns were emerging among these pioneer clinics. Demonstration clinics had been taken over by the staffs of the state hospitals, communities had rallied to financial support to obtain increased service, clinics housed in hospitals had begun to function as training centers, schools had begun to use clinics for the solution of problems, and contacts with children had contributed valuable information to psychiatrists. The child-guidance movement had won prestige both in professional and in popular esteem.

In 1926, the division started the Quincy Clinic,† which proved to be one of the most successful and is still in the process of expansion. It serves a wide circle of surrounding towns and receives a large percentage of its cases from public schools. For a

few years, it attempted to meet the pressure by using a double staff, then increased service to two sessions weekly in January, 1943, and is now in the process of obtaining community funds for enlarged scope through the interest of a local sponsoring committee.

In Worcester a clinic for children was organized¹⁶ during this year under the name of the Child Guidance Clinic and embarked on its eminently successful career. In the following two years, community interest and support increased so that in 1929 it was able to offer full-time service with the financial participation of the Child Guidance Association of Worcester.¹⁷

At that time, the traveling school clinics began to be under continual pressure to furnish treatment as well as diagnostic service to children who were not defective but who were in need of help, and many cases of this type were served.¹⁸

The year 1927 saw eight clinics of the division and five clinics of the state hospitals well under way. Methods used in Massachusetts were being studied and adopted by other states and other countries.¹⁹ Inquiring visitors were frequent. Schools of social work had co-operated since 1923 in offering related courses and were sending students to the clinics for field training. Social workers were eager to enter the field, but the demand for trained personnel far exceeded the supply.

During 1927, the Taunton State Hospital opened a clinic at the hospital and also one for adults and children at the Sturdy Memorial Hospital in Attleboro.

On December 1, 1927, the Habit Clinic at the New England Hospital for Women and Children in Roxbury, which had previously been conducted under private auspices by Dr. Thom, came under the jurisdiction of the division. This clinic worked in co-operation with the hospital and served a large residential district in the southern section of Boston. It was chiefly a treatment clinic, holding one session weekly and maintaining quite steadily an average attendance of 10 cases per session over a period of sixteen years, until it was consolidated with the Southard Clinic in October, 1943.

In July, 1928, a new venture was initiated²⁰ giving clinic service monthly to tuberculous children at the North Reading Sanatorium. A careful survey was made for the purpose of improving educational facilities, resulting in the introduction of occupational therapy. Considerable social case work was done in co-operation with the Department of Public Health. Owing to the pressure of work in community clinics, this service was changed in 1939 to a consultation service on call.

In October, 1929, the division organized another community clinic in Norwood, sponsored but not financed by an active group of social-minded women. It was housed at the Norwood Hospital and served towns and rural districts to the south and west of

*One of these was opened at the Boston Dispensary on December 5, 1924, and was consolidated with the Southard Clinic at the Boston Psychopathic Hospital in October 1943. The second was established on December 3, 1924, at St. John's Hospital, Lowell, and was closed in 1927. It was reopened at the School Clinic Building on January 22, 1932, and was moved to Lowell General Hospital in 1933. The third was opened in December 1924 at the Town Hall, Reading, and closed on September 30, 1939. The fourth was opened on March 12, 1925 at the Beverly Health Center and was transferred to the Danvers State Hospital on April 13, 1932.

†It was opened on October 7, 1926, at the Quincy Dispensary, was conducted at the Woodward School from 1931 to 1943, and has been at the Children's Health Center since 1943.

Boston, and was well patronized by school principals and nurses. Restrictions of transportation in 1943 necessitated the closing of this clinic in October, and its cases were referred to the Southard Clinic in Boston.

The years 1929, 1930, 1931 and 1932 were significant in the establishment of ten state-hospital clinics.* The Fall River Clinic was a general psychiatric clinic until 1940, when it became a child-guidance clinic. These clinics, with the exception of Quincy, have continued to function on a weekly or monthly basis. The Quincy Clinic undertook the treatment of court cases and adolescents who were above age for the clinic conducted by the division in Quincy. After February, 1943, services were rendered only on call from the court or schools, and treatment cases were referred to the Division Clinic, which had for some time been accepting adolescents as well as younger children.

It had been the ambition of the division to have clinical facilities accessible to all citizens of the Commonwealth, but up to that time services had concentrated in the more populous eastern section. In May and June, 1931, demonstration clinics were instituted in Northampton and Holyoke and, following the six-month demonstration period, they were transferred to the auspices of the Northampton State Hospital in December, 1931.

In the year 1932, the division reopened the clinic at Lowell. This was a new type of co-operative venture undertaken at the request of the school department, which felt the need of a special school survey and the instruction of teachers in the principles of mental hygiene. The clinic was later moved to the Lowell General Hospital, and has changed in character because of its association with the hospital and its less central location. At the time of this resumption of responsibility, the Danvers State Hospital took over from the division the well established clinic at Beverly. In October of the following year, the Danvers State Hospital opened a clinic at the Community Health Center in Newburyport.

The year 1933 rounded out ten years of service of the state child-guidance clinics,²⁰ and various trends were in evidence. The original intention of the division to turn over its demonstration clinics to state hospitals as psychiatric centers of their respective districts had been carried out in six instances, and the hospitals had initiated clinics of their own in eight communities. The division itself was conducting nine clinics, which were acquiring

an aspect of permanence. Five of these were so-called "community clinics," affiliated more closely with schools and social agencies than with medical centers. Advantages were apparent in each type. The community clinics had become a part of community life, and were influential in the education of teachers through school conferences and in the education of parents through mothers' clubs and parent-teacher associations. The emphasis was on the problems of the normal child. The social and economic level of the patients was somewhat higher than that in the clinics that were affiliated with hospitals. The latter had advantages of medical services whenever needed and had a somewhat larger proportion of serious cases. These clinics also furnished an opportunity for instruction of medical interns and student nurses in the recognition and treatment of neurotic symptoms.

This period saw the beginning of special services in the clinics, such as speech correction, remedial reading and occupational therapy.

During these first ten years, the division had registered 5043 cases, which furnished a basis for analysis and research. Special studies and published articles by clinic personnel had become a part of the campaign for mental health.

The pressure of applications for intake necessitated the formulation of selective criteria for acceptance of cases suitable for clinic therapy, but the fact that the service was free under state support placed the clinics under obligation to accept maximum loads. This condition produced in an aggravated form the same dilemma that beset the generously staffed demonstration clinics of the Commonwealth Fund²¹ — the question whether to give intensive therapy to a few or more generalized treatment to many. Psychoanalytic procedure was impossible under the circumstances and would have met with popular prejudice, in fact, it was indicated in only a few cases that could be referred to private agencies, such as the Judge Baker Foundation, the New England Home for Little Wanderers and the Psychiatric Clinic of the Massachusetts General Hospital. Psychiatrists trained under various schools of thought directed their efforts toward improving parental attitudes and modifying the personal problems of children. In some cases the mother needed therapy as much as the child, and the social workers began to undertake this responsibility under the direction of the psychiatrists. The year-by-year discussions of all these problems in reports and bulletins give a dramatic picture of a pioneering effort with successes and failures but always un-failing enthusiasm.²²

The last ten years, from 1933 to 1943, have constituted a period of stabilization rather than of expansion. The division had reached the financial saturation point and could establish new clinics only by closing its less effective ones. Some new state

*These were as follows: Quincy, November 1929, auspices of Medford State Hospital at Quincy School Annex (closed February 1945); Fall River, 1930, auspices of Taunton State Hospital at City Hall Annex; Norwood, 1930, auspices of Medford State Hospital at Norwood Hospital (closed June, 1935); Gardner, July 1930, auspices of Gardner State Hospital, at Gardner High School, Fitchburg, July, 1930, auspices of Gardner State Hospital at Academy Street School, Haverhill, January, 1931, auspices of Danvers State Hospital at Haverhill High School (closed February 1944); Lawrence, January 1931, auspices of Danvers State Hospital at International Institute, Gloucester, January 1932, auspices of Danvers State Hospital, at Hovey School (closed June 1934); Warwick, 1933, auspices of Gardner State Hospital, at Central School and Athol, October, 1933, auspices of Gardner State Hospital at Red Cross Headquarters.

hospital clinics were started* The Salem Clinic has made a valuable contribution, the Waltham Clinic was doing intensive and effective work when it was closed for lack of personnel, the Amherst and Greenfield clinics served a hitherto neglected area.

In 1938, the Springfield Clinic expanded into a full-time clinic with financial contribution from the Community Chest. The school department furnished excellent quarters, and a sponsoring group formed the Guidance Clinic Association, which has acted in the capacity of an advisory board of directors.

The chief innovation of the division was the establishment of a clinic in Brockton on September 30, 1938, in co-operation with the school department, which has provided housing and stenographic service. In October, 1939, it expanded to two sessions weekly and still has an extremely heavy case load, obviously needing more service. This clinic exemplifies the type of clinic that can be developed through an intelligent educational policy to reach children of all ages. The clinic offers special services for speech correction, remedial reading and occupational therapy. Special classes for superior children have been in operation in the school system, with close supervision from the clinic. Brockton has an effective group of social agencies that co-operate with the Guidance Clinic both in case work and in a community program for mental health.

The division opened trial clinics in Hamilton (1940-1941) and Marblehead (1940-1942), which were discontinued because of lack of referrals by the communities. The Barnstable Clinic, opened in September, 1942, is developing as a mental-hygiene center for southeastern Massachusetts and Cape Cod, holding four sessions monthly at the Hyannis Town Hall.

The Quincy Clinic, which is a school and community clinic, has outgrown its original setup. In January, 1943, it added a second weekly session, and in December, 1943, moved to quarters in the Child Health Center. Community interest has resulted in the formation of the Guidance Association, which has obtained supplementary financial support for enlarged services. The Guidance Association is a member of the Quincy Council of Social Agencies, which is extremely active and promotes efficient social work in the city.

The new Southard Clinic, opened in Boston in 1943, is a different type of clinic and contemplates an extension of service for which the division has been clamoring for ten years. This clinic is a consolidation of the children's work of the Out-Patient

Department of the Boston Psychopathic Hospital with three division clinics that were discontinued to provide personnel. It is housed at the Boston Psychopathic Hospital and has the advantage of access to the specialized facilities of the institution for the diagnosis and treatment of serious cases. A definite disadvantage is found in the objection of many parents to any contact with a mental hospital, especially one that is stigmatized with the prefix "psycho-." This troublesome problem could be met by the erection of a separate building that would furnish headquarters for the Division of Mental Hygiene and the Division of Mental Deficiency, and would have a ward for the observation and treatment of young psychotic patients. Massachusetts has lagged behind other states in its failure to provide for segregation of such patients, who at present must mingle in the wards of mental hospitals with adult patients, an environment that is extremely detrimental to recovery.²³

The changes that have taken place in the last ten years have been in the direction of stabilization and efficiency. On January 1, 1944, nearly 12,000 cases had been accepted by the division clinics (exclusive of Springfield and Worcester) for diagnosis and therapy. The pressure of quantity has caused emphasis to be laid on essentials, economy of effort and selectivity of service. Co-operative resources have been utilized with mutual benefit. Student training has kept social workers up to date in methods of social therapy and has provided the clinics with assistance in case work. Special services in speech and reading, as well as hobby classes, have enhanced the value of the clinics. The constructive aim of helping children to attain a normal emotional maturity has been contagious and inspiring.

Twenty years of experiment and demonstration could not have been carried out on so large a scale without state financing. This provided security, minimized the effect of incidental failures, allowed changes of location and exchanges of responsibility between hospitals and the division, and made possible a statewide program for mental health. The benefits of such assistance outweigh the burdens and restrictions that are implicit in a state-supported service.

Much credit for the success of the child-guidance movement must be attributed to the gifted and forward-looking psychiatrists who initiated it and carried it on.

MEDICAL PROGRESS

MYCOTIC INFECTIONS*

JOHN GODWIN DOWNING, M D,† AND NORMAN F CONANT, Ph D ‡

BOSTON, MASSACHUSETTS, AND DURHAM, NORTH CAROLINA

NUMEROUS medical problems have been created by sudden changes in the living habits of large groups of the population. Emigration to different localities, the influx of workers into industries with which they have had no previous contact and the grouping of thousands of men in camps, both in this country and abroad, have contributed to the shifting problems of health. Diseases heretofore restricted to or endemic in certain areas or peculiar to certain industries have appeared sporadically and at times with epidemic proportions in areas or industries where they had not previously been reported. It is now necessary, therefore, that the practicing physician constantly focus his attention on an increasing horizon of infectious diseases.

Among such diseases, the mycotic infections have gained great importance. Previous epidemics of so-called "athlete's foot" among civilian members of social, fraternal or athletic organizations, due to the widespread use of showers and swimming-pool facilities, have become overshadowed by the rate of infection and seriousness of this disease among the troops. Safiron¹ has reported fungus infection as one of the five diseases most frequently attacking the skin of fighting men, and estimates the incidence of infection in various groups to be as high as 40 to 90 per cent. Downing² has also reported on the increasing problem of fungus infections in various camps. According to Goldstein and Louie,³ alarming numbers of American troops have acquired coccidioidomycosis while training in endemic areas in this country where *Coccidioides immitis* is known to occur in the soil. On return to civilian life,

these patients will scatter to all sections of the country and will necessitate the inclusion of coccidioidomycosis in the differential diagnosis of pulmonary infections outside of areas where the disease is known to be endemic. From the few samples cited above, it can readily be seen that the medical profession must gain a better understanding of the prevention and control of fungus infections.

With the exception of a few endemic areas, the geographic distribution of fungus infections is worldwide. The distribution of such diseases depends in reality on their recognition alone, and their frequency of occurrence demands that they be considered in the differential diagnosis of any infection of the skin or internal organs. It is the purpose of this article to present a résumé of the field of medical mycology as an aid to those who are comparatively unfamiliar with the types of infection produced by fungi.

Fungus infections can be conveniently divided into four major categories namely, superficial mycoses, dermatomycoses, subcutaneous mycoses and systemic mycoses. These will now be considered.

SUPERFICIAL MYCOSES

Included in the category of superficial mycoses are a few fungus diseases caused by a heterogeneous group of organisms, considered to be saprophytic species but occasionally producing superficial lesions on the skin or hair.

Tinea versicolor

Tinea versicolor is the most superficial of all the fungus diseases, with subjective symptoms lacking or with slight pruritus, the lesions involving usually the trunk but occasionally the neck, face, axillae and arms. The disease is characterized by a yellowish or brownish macular eruption and is caused by

†Professor of dermatology and syphilology Tufts College Medical School and professor of dermatology Boston University School of Medicine.

‡Associate professor of bacteriology and mycology Duke University School of Medicine.

Malassezia furfur Although cultures of this fungus have been obtained,^{4, 5} the clinical diagnosis is confirmed by a microscopic examination of potassium hydroxide preparations of the furfuraceous scales covering the colored areas. In such preparations the fungus appears as clusters of round, thick-walled, budding forms intermixed with branching mycelial fragments. Treatment is directed toward the removal of the infected scales by daily hot, soapy baths, followed by an application of a 20 per cent aqueous solution of sodium hyposulfite.

Erythrasma

Erythrasma is a somewhat chronic superficial fungus infection confined to the skin of the axillary, pubic or genitocrural areas. The disease is characterized by sharply circumscribed maculopapular lesions having a reddish-yellow to reddish-brown pigmentation with overlying furfuraceous scales that feel greasy. The causative fungus, *Actinomyces (Nocardia) minutissima*, has been cultured but, as with tinea versicolor, the clinical diagnosis is confirmed by a microscopic examination of potassium hydroxide preparations of material scraped from the lesions. Such preparations reveal short, delicate, branching filaments 1 micron in diameter that are consistent in size with those seen in species of *Actinomyces*. The treatment is the same as that described for tinea versicolor.

Trichomycosis

Trichomycosis is an infection of the axillary or pubic hairs without involvement of the surrounding skin. The disease is characterized by lusterless, brittle hair with yellow, red or black concretions extending for some distance or occurring as isolated nodules along the hair shaft, and is caused by *Actinomyces*. Chromogenic cocci mixed in the mucilaginous material composing the nodules are responsible for the red or black pigmentation of the colored varieties.⁶ Microscopic preparations in potassium hydroxide reveal numerous cocci mixed with short, branching, thin mycelial fragments. Effective treatment involves shaving the hair and daily treatment with 3 per cent sulfur ointment or application of a 1:1000 solution of mercury bichloride.

Piedra

Piedra, a disease of the hair of the head or face, is known to occur in two varieties — black piedra, confined to the tropics and caused by *Piedra hortae*,⁷ and white piedra, occurring in the tropics and also in Europe, caused by *Trichosporon beigeli*.⁸ The disease is characterized by black or light-colored, hard nodules adherent to the hair shaft. As in trichomycosis, the surrounding skin is not involved. Because of the nodules the hair feels gritty when pulled between the fingers. The nodules of the black variety are composed of a compact

mass of wide, closely septate, thick-walled filaments, among which are scattered asci containing eight fusiform ascospores. The nodules of the white variety are composed of wide, closely septate filaments that break up into rectangular elements, budding cells and cocci. Microscopically these nodules are quite different from those seen in trichomycosis. Treatment consisting of vigorous shampoos or shaving, followed by the application of a 1:2000 solution of mercury bichloride or a 3 per cent ammoniated mercury ointment is usually effective.

Otomycosis

Otomycosis is a troublesome disease of the ear canal from which a wide variety of fungi have repeatedly been isolated. The majority of these fungi are saprophytic species, and their role in the disease is not completely understood. The infection is characterized by an exudative inflammation of the ear canal, which may extend to the external ear. Epithelial debris forms somewhat large masses that may interfere with hearing. An extensive pruritus, more noticeable at night, usually accompanies the infection. Treatment is directed toward the removal of all debris and keeping the ear canal dry.⁹⁻¹¹ Drugs having a bactericidal action should be used as a paint; these include a 1 per cent aqueous solution of gentian violet, a 1 per cent aqueous solution of silver nitrate and a 1 per cent aqueous solution of brilliant green. The sulfonamides, especially sulfanilamide, used as a dusting powder have also been found extremely useful. It can be seen that the use of these drugs is aimed at a possible primary bacterial infection of the ear canal as the underlying cause of the disease. Careful observation must be maintained, because of the danger of sensitization to the sulfonamides.

DERMATOMYCOSSES

Fungus infections belonging to the category of dermatomycoses are also superficial diseases of the hair, skin or nails, but they are caused by a related group of fungi, the dermatophytes. This group includes the genera *Trichophyton*, with about twelve species, *Microsporum*, with three species, and *Epidermophyton*, with a single species.

Microscopical examination of the infected hair, skin or nails in a 10 to 40 per cent potassium hydroxide preparation is the best method of ensuring an accurate diagnosis of this type of infection. Several modifications of this technic are advocated for preserving specimens for teaching purposes.¹²⁻¹⁵ Wood's light (filtered ultraviolet light), which causes infected hairs to fluoresce, is a great aid in the diagnosis and management of ringworm infection of the scalp.¹⁶ Hairs that fluoresce under this light should be examined microscopically for the presence of fungi. Since successful treatment de-

ends on complete epilation of the infected hairs, the Wood's light serves as an important aid in discovery and ultimate eradication of these foci of infection

Such preparations as are described above confirm the clinical diagnosis of fungus infection, but they cannot be used for the identification of the invading fungus. Trichophyton, Microsporum and Epidermophyton are similar in appearance when seen in potassium hydroxide preparations of infected skin or nails. Infected hair, however, usually reveals a definite mode of invasion by the genera Trichophyton and Microsporum. Since growth outside or within the hair shaft, or both, serves only as a generic character, it is necessary to culture the infected material to determine the species. It can be therefore seen that a complete identification of the invading fungus in all cases, whether the hair, skin or nails are affected, is possible only by obtaining cultures.

Such cultures are best secured by inoculating Sabouraud's glucose agar slants with several pieces of the infected material. When growth becomes established — in two to three weeks — preparations of the cultures in lactophenol cotton blue for microscopic examination reveal structures that allow their identification. The most useful structures for this purpose are the spore types and accessory organs.¹⁶⁻¹⁸

The genus Microsporum is characterized by numerous large, fusiform (spindle-shaped) macroconidia (fuseaux) and relatively few small, single-celled microconidia (aleuriospores). Whereas the species *M. canis* and *M. gypseum* produce macroconidia in abundance, *M. audouinii* produces abortive types of macroconidia or none at all. In culturing these species on rice medium these differences become apparent.¹⁹

The genus Trichophyton is characterized by a scarcity of clavate (club-shaped) macroconidia and numerous small, single-celled microconidia produced in grapelike clusters or singly along the hyphae. The macroscopic appearance of the cultures also serves to identify the species Trichophyton. The type of growth — powdery, cottony, smooth or waxy — the configuration and the pigmentation allow these fungi to be identified as *T. rubrum*, *T. rosaceum*, *T. gypseum*, *T. crateriform* or *T. faviform*. These species are not numerous, but can usually be identified only by those familiar with them.

Identification of the single species of the genus Epidermophyton, *E. floccosum*, presents no difficulty. The fungus grows on Sabouraud's medium as a powdery, sulfur-colored fungus and produces clusters or groups of short, stubby, few-celled, club-shaped macroconidia. No microconidia are produced by this fungus in culture. As the growth becomes older the culture reveals numerous chlamydospores.

The dermatomycoses show a wide variety of

clinical types, depending somewhat on the location of the infection on the body and the type of fungus causing the infection. It is not possible, however, constantly to associate the same fungus with a particular type of lesion, that is, favus may be caused by *T. (Achorion) schoenleinii*, *T. (Achorion) violaceum*²⁰ or *M. (Achorion) gypseum*.²¹ Whereas distinct clinical types of infection are recognized, the etiologic agent can be identified only by culture.

Tinea Pedis

This infection is known as "athlete's foot," dermatophytosis, epidermophytosis and so forth, but is probably better designated as tinea pedis. It is the most frequent of all the fungus infections, and the one causing the greatest concern among the armed forces. A simplification of the clinical types of this infection includes the acute, subacute and chronic forms caused by species of Trichophyton and by *Epidermophyton floccosum*.

The acute infection is characterized by vesicular or vesiculopustular eczematoid lesions, which usually begin between the toes but spread rapidly over the feet or along the soles. The vesicles contain a clear serous fluid until secondary pyogenic infection has taken place. This secondary infection produces ulcerating lesions, which spread rapidly. The foot becomes edematous and painful, with a rapidly developing cellulitis, lymphangitis or lymphadenitis. During this phase systemic reactions may occur.

Vigorous treatment of the acute infection must be avoided until the symptoms have disappeared. Compresses of a saturated solution of boric acid, a 1:4000 solution of potassium permanganate or physiologic saline solution should be used constantly, with the patient in bed and the feet elevated. If the secondary pyogenic infection is caused by a staphylococcus or streptococcus, penicillin should be used. After the acuteness of the lesions has subsided, half-strength Whitfield's ointment or 10 per cent sodium propionate in a water-soluble base may be employed. Treatment should be continued for a week or two after the lesions have healed. A dusting powder should be used as a prophylactic.

The subacute infection is characterized by vesicles or vesicopustules of a spreading type, usually starting between the toes. Absence of a superimposed secondary pyogenic infection of the vesicles permits this type of infection to be managed more easily than otherwise. A lymphangitis or lymphadenitis may result, however, and conservative treatment by compressing should precede the use of keratolytics or fungicidal agents. The same kind of treatment as used in the acute infection is often necessary.

The chronic infection is characterized by fissuring between the toes and an accumulation of soggy dead tissue. Hyperhidrosis is usually present, and treatment must be directed toward controlling this condition. Ointments containing a keratolytic (half-strength Whitfield's ointment) can be used to re-

move the dead and infected tissue. Care should be taken to avoid irritating the skin, which may result in an acute flareup. Dusting powders employed as a prophylactic and also as a drying agent are beneficial.

That there is no specific method of treating cases of *tinea pedis* has been clearly demonstrated by the recent appeals of the medical services of the Army and Navy for help in combating this type of infection. This fact has brought about in vitro studies of new drugs that might prove to be more effective fungicidal or fungistatic agents²²⁻²⁴. Concise outlines of management have also been published, as well as data concerning the clinical trial of new drugs. Peck and Schwartz²⁵ have outlined a plan of treatment and have given numerous prescriptions that prove helpful in various types of infection. Crittenden and Joiner²⁶ have used cotton hose impregnated with copper sulfate or copper acetate. Bograd²⁷ has used ethyl chloride as a spray to cover infected areas. Wallace et al²⁸ have used a chlorophyl ointment. Recently Keeney and Broyles²⁹ have reported on the use of propionate acid and the higher fatty acids as beneficial therapeutic and prophylactic agents. No standard method of treatment has, however, resulted from these studies.

Recurrence of infection may result from a previous inadequate treatment of the infected foci or from reinoculation through contaminated contacts. Prevention must therefore include a thorough search for remaining foci of infection and adequate instructions to the patient concerning how contacts may best be avoided.

Shoes, socks, stockings and clothing may be sterilized by formaldehyde vapor. The articles should be placed in a container with a tight-fitting cover, along with old rags or crumpled newspapers soaked with the formaldehyde. The fumes should kill all fungus material in a period of twenty-four hours. These articles are then well aired to avoid a subsequent dermatitis. Cotton socks may be boiled for twenty minutes or soaked in a 1 per cent solution of liquor cresolis saponatus *U S P* overnight and washed in cold water. Women's stockings may be soaked in 90 per cent grain alcohol for twenty-four hours.

A dusting powder (2 per cent salicylic acid, 3 per cent zinc stearate, 6 per cent boric acid, 10 per cent starch and 79 per cent powdered talc) should be used in the shoes and socks and dusted on the feet. Also, the feet may be painted once or twice a week with a sodium propionate lotion, containing 8.2 per cent sodium propionate, 1.2 per cent propionic acid and 10 per cent N-propyl alcohol. The feet should be kept clean, clean socks should be worn every day, and if excessive perspiration is serious, a drying agent (aluminum acetate) should be occasionally used.

The patient should be warned about possible places of contamination, that is, shower baths or

bathroom floors. Newspapers or similar material that is easily disposed of should be used on the bathroom floor instead of mats. The tub should be thoroughly cleaned and dried after use. A rubber mat for the shower floor should be washed and placed in the sun to dry. Slip-on rubber sandals can be worn in the showers, and to and from them in gymnasiums and swimming pools. Too much reliance should not be placed on the foot baths to be found in these places. Often they are hurriedly used, become diluted or contaminated with organic materials and are not frequently freshened. All these factors, together with the doubtful fungicidal activity of the various types of foot baths, advocate the destruction of the value of this type of prophylactic measure.

Tinea Corporis

Fungus infections of the glabrous skin, which have been designated as *tinea glabrosa*, *tinea circinata*, ringworm of the smooth skin and so forth, are caused by species of *Microsporum* and *Trichophyton*. The lesions resulting from this type of infection vary greatly, and the clinical diagnosis should be confirmed by laboratory examinations of material obtained from the lesions and by culture.

Infections on the glabrous skin vary from extremely superficial scaly annular lesions to an erythematous squamous or deep granulomatous type. The usual lesion begins as a red papule, which spreads peripherally while healing in the center. The erythematous border has many minute vesicles and pustules, with some crusting. This type of circular lesion with reddened active border and healing scaly center is typical of ringworm, or *tinea circinata*, of the skin.

If the lesion begins as a vesicle or group of vesicles that break down and form a rather large crusted area with peripheral vesiculation but no central healing, the lesion is usually referred to as the eczematous type. Such lesions may be single or multiple, coalescing to form large configurations.

Suppurative, deep, granulomatous lesions begin as red, indurated nodules centered around perifollicular abscesses. Discharge of pus and ulceration of the skin are indications of a severe infection.

The type of infecting organism cannot always be determined by the clinical appearance of the lesions. It is now well known that a single fungus can produce different types of lesions and that different fungi can produce similar lesions. In some cases, however, certain species are somewhat consistent in the type of lesion that they produce. The configuration of the lesions found in *tinea imbricata* of the tropics and of South and Central America is characteristic of an infection produced by *T. concentricum*. Also, the cuplike structures (scutula) on the scalp and glabrous skin in *tinea favosa* are somewhat characteristic of invasion by *T. (Achorion) schoenleinii*. It must be remembered, however, that

both *M. (Achorion) gypseum*²¹ and *T. (Achorion) violaceum*²⁰ have also been isolated from typical avus lesions. It has been pointed out that *T. rubrum* (*purpureum*) also produces a somewhat specific reaction.²⁰

The only reliable means of determining the type of invading fungus is culture and identification of the resulting growth. Material for culture is obtained from the erythematous border of the lesions by scraping or by curetting the tops of vesicles. This material should be examined microscopically in potassium hydroxide and cultured on Sabouraud's glucose agar slants. Since an accurate prognosis depends on the type of infecting organism — that is, *T. rubrum* and *T. schoenleinii* produce stubborn, resistant infections, — cultures should be obtained and identified whenever possible.

Treatment of tinea corporis is not difficult unless the invading fungus happens to be either of the two mentioned above. Even in these cases, successful treatment is possible, but it must be prolonged and more intensive.

Ointments (5 per cent ammoniated mercury, 3 per cent salicylic acid and 5 per cent ammoniated mercury or 3 per cent precipitate sulfur and 3 per cent salicylic acid) or a 3.5 per cent tincture of iodine should be applied twice daily. When the vesicular lesions become crusted, it is necessary to remove the crusts and thoroughly rub in the ointment. Cure should be effective in two weeks.

Lesions on the glabrous skin that simulate in every detail the clinical appearance of active fungus infections occasionally fail to heal after appropriate treatment. Serious consideration should be given to such cases to establish whether fungi are locally present in the lesions or whether the lesions are the result of hypersensitivity, that is, dermatophytids or secondary eruptions occurring in a sensitized person. These dermatophytids may occur anywhere, but are found particularly on the palmar aspects of the hands as a result of a hematogenous spread of a fungus or its products from a primary focus of infection elsewhere on the body. These primary foci are usually confined to the feet,³¹ are unnoticed by the patient, and sometimes are discovered only after a thorough investigation. Occasionally, too vigorous treatment of tinea pedis causes a generalized dermatophytide reaction. It is therefore necessary to examine microscopically material from lesions of the glabrous skin to establish the presence or absence of fungi. When fungi are not seen in such material, the primary focus of infection must be found and treated. In such cases the dermatophytide reaction subsides as the primary focus heals.

Tinea Cruris

Tinea cruris, or ringworm infection of the groin, also known as tinea inguinale, eczema marginatum, jockey itch, dhotie itch and so forth, is a circum-

scribed, well demarcated infection of the crural region usually caused by *Epidermophyton floccosum* and occasionally by species of *Trichophyton*.

This infection was known to Harz²² in 1871, at which time he cultured *E. floccosum* from it. The lesions are usually bilateral, elevated, papular, scaly, red areas with a sharply demarcated border of vesicopustules. Although the inner thighs are the areas usually involved, the infection may spread to the sacrum or involve the pubic areas. The disease is more frequent in males than in females but is often seen in the latter. Epidemics have been reported³² in regions where people were living closely together under crowded conditions.

Treatment with ointments (half-strength Whitfield's ointment and 3 per cent precipitated sulfur and 3 per cent salicylic acid in petrolatum) or with Castellani's paint is usually effective in two weeks. Occasional stubborn cases necessitate prolonged treatment. Careful laundering of wearing apparel is important to avoid reinfection.

Tinea Unguium

Ringworm of the nails or onychomycosis of the hands or feet usually accompanies tinea pedis or infection elsewhere on the body, but can occur as the only presenting lesion. This disease is caused by species of *Trichophyton*, *Epidermophyton floccosum* and *Candida (Monilia) albicans*.

Nails infected by the dermatophytes show yellowish discoloration, and become lusterless, friable and thickened, often with great amounts of material beneath the nail. Paronychia is not an accompanying symptom. Material should be scraped from the discolored or friable areas and from beneath the nail for microscopic examination and culture. The fungi appear as branching filaments when the infection is caused by the skin fungi.

Nails infected with *C. albicans* have an accompanying paronychia. The nails become thickened, grooved and brownish but remain translucent and do not become brittle. This fungus appears as small, budding, egg-shaped cells in the infected material.

Treatment of nails infected with dermatophytes consists of filing or scraping the infected portions of the nail as thoroughly as possible. The scraped nail may be painted with chrysarobin (20 per cent in chloroform), taking care to avoid contact with the skin, rubbed with sulfur salicylic acid ointment (10 per cent each of precipitated sulfur and salicylic acid in equal parts of lanolin and rose water ointment) or painted with 1 per cent iodine in alcohol. Before each medication the old material should be scraped off the nail. Surgical evulsion of a nail is sometimes necessary. Nails infected with *C. albicans* should also be scraped and the nails soaked in a 1:4000 aqueous solution of potassium permanganate three times daily, followed by a paint containing 1 per cent gentian violet or an ointment

containing 5 per cent ammoniated mercury. Whether infection is caused by the dermatophytes or by *C. albicans*, the treatment is prolonged and may last for months before a cure can be expected.

Tinea Barbae

Ringworm of the beard, known as sycosis parastitica, tinea sycosis and so forth, is a stubborn, chronic fungus infection of the bearded region of the face and neck, with rare involvement of the upper lip, caused by species of *Trichophyton* and *Microsporum*.

Two types of infection may be encountered in the bearded area: a superficial dry lesion with a central scaly area and an active vesiculopustular periphery or areas of perifollicular pustules with lusterless hairs progressing to red, deep-seated nodules and boggy masses with adenitis of the regional lymph nodes. Such areas are undermined, and extrusion of purulent material occurs, with resulting crust formation. The hairs are brittle and easily epilated. Involvement of the upper lip has been reported,^{34, 35} but is rare. Microscopical examination of material from the lesions is the only means of determining the fungus nature of the infection.

The patient should be instructed in the sterilization of his shaving articles. Manual epilation of all infected hairs is necessary for complete cure. In some cases x-ray epilation may be necessary. Compresses of hot boric acid solution, a 1:4000 aqueous solution of potassium permanganate or Vlemminckx's solution, diluted 1:10, followed by a 5 per cent ammoniated mercury ointment rubbed well into the skin, should prove successful.

Tinea Capitis

Ringworm infection of the scalp, tinea capitis, is essentially a disease of childhood, with a variety of clinical appearances, and is caused by species of *Trichophyton* and *Microsporum*.

The appearance of lesions on the scalp caused by the dermatophytes varies according to the type of infecting fungus and the response of the patient. Some species of *Microsporum* and *Trichophyton* cause an inflammatory reaction leading to large, boggy, tumorlike masses (kerion). In such areas, the infected hairs are dislodged easily and there is a tendency to spontaneous cure. Other species do not evoke an inflammatory reaction and are more difficult to manage and treat.

Infection by species of *Microsporum* usually results in a few scaly, gray patches in which the hairs are broken off 3 to 4 mm from the surface of the scalp. Microscopically, the hairs are seen to be surrounded by a sheath of angular spores arranged in a mosaic pattern.

Infection by species of *Trichophyton* results in a variety of lesions depending on the particular species involved. Infection by *Trichophyton schoenleinii*, the usual cause of favus, is characterized by the

formation about the hair follicle of a yellow crust with a depressed center, giving a cuplike appearance. Such cups, or scutula, contain mycelium and cellular debris and are pierced by the hairs. Microscopically, the hairs are seen to be of the endothrix type, with invasion of the fungus inside the hair shaft. A seborrheic eczema type of lesion with diffuse superficial scaling may also be caused by this fungus. Examination of the hairs is necessary for a differential diagnosis. Infection by other endothrix species (*T. violaceum* and *T. acuminatum*) may be characterized by small, scattered, scaly crusts over the scalp with the hairs broken off at the surface. The follicles protrude and have a black center (black-dot ringworm), or the hairs may not be broken off but be folded in the scales of the crusts forming the lesion (*T. tonsurans*).

Species of *Trichophyton* belonging to the ectothrix group, such as *T. mentagrophytes* (*gypseum*), in which the fungus is seen outside and surrounding the hair shaft as parallel rows of spores, produce inflammatory and suppurative lesions leading to kerion formation. This type of infection may be mistaken for pyoderma, and the only satisfactory diagnosis is that based on a microscopic examination of the hair. Since an inflammatory reaction may develop a sensitivity of the skin, patients with kerion of the scalp may exhibit rashes on the trunk or extremities. This type of reaction has been known for some time^{31, 36} and, as mentioned previously under tinea pedis, is the result of a hematogenous spread of the fungus or its products from a primary focus of infection. Such lesions, dermatophytides, do not contain the fungus, are an allergic manifestation and disappear as the primary focus heals.

Treatment of tinea capitis must be guided by the type of fungus causing the infection. *M. audouinii*, *T. schoenleinii*, *T. violaceum* and *T. tonsurans* cause resistant infections that are difficult to manage. The lesions of *M. audouinii*, however, tend to heal spontaneously as puberty is reached. *T. schoenleinii* and *T. violaceum* produce lesions that do not heal spontaneously at puberty but remain through the adult years. On the other hand, *M. canis*, *M. gypseum* and *T. mentagrophytes* cause lesions that may heal spontaneously at any time, especially if an inflammatory reaction is induced. It is therefore necessary to obtain cultures and identify the fungus from each case for a proper evaluation of prognosis and treatment.

Treatment is directed toward the removal of all infected hairs. Wood's light is invaluable as an aid in detecting these hairs and should be constantly used during the management of the disease. Hairs infected with the following fungi fluoresce under this light: *M. audouinii*, *M. gypseum*, *M. canis*, *T. schoenleinii*, *T. violaceum*, *T. tonsurans* and *T. mentagrophytes*.

A conservative type of treatment may be used when the infection is one that is likely to heal sponte-

ineously. An ointment containing 5 per cent ammoniated mercury or 10 per cent sulfur ointment with iodine crystals should be rubbed well into the scalp. Daily shampooing, with a stiff brushing, removes the loosened infected hairs. The shampoo should be followed each time with the ointment.

Treatment of the infection, which is likely to remain until puberty or be carried over into adulthood, demands better methods of epilation. Manual epilation with forceps is practical only when small areas of the scalp are infected, and should be repeated every four days. For larger areas, the hair should be clipped close and adhesive plaster applied tightly and pulled off to remove the loosened hairs. An ointment of 10 per cent ammoniated mercury rubbed into the scalp will prevent infection of healthy areas, and an adhesive-plaster patch over the infected areas will prevent the loosened hairs from falling out to cause reinfection or epidemics. Roentgen-ray epilation may be desirable in certain cases, but should be done only by one fully experienced in its use.⁴⁷ Thallium acetate should be used only when contraindications are lacking and the patient is hospitalized.

Estrogenic substances³⁸ in the treatment of tinea capitis caused by *M. audouinii* and trichophyton³⁹ as a therapeutic agent for ringworm of the scalp have not as yet given satisfactory results.¹⁶

SUBCUTANEOUS MYCOSES

Infections of the subcutaneous tissues are caused by a wide variety of fungi, which produce lesions simulating those of syphilis, tuberculosis, and pyogenic infections as well as granulomas and neoplasms. Three of the frequent types of such infections will be discussed below.

Chromoblastomycosis

This disease, often referred to as chromomycosis or verrucous dermatitis, caused by *Hormodendrum pedrosoi*, *H. compactum* and *Phialophora verrucosa* and thought previously to be of rare occurrence in the United States, has gained widespread interest, owing not only to the increased number of cases encountered in this country but also to the atypical forms of the disease that have been reported.

Chromoblastomycosis is a disease, usually of the lower extremities, producing unilateral lesions of warty papillomatous vegetations (verrucous dermatitis). Fibrosis and blocking of the lymphatics produce an elephantiasis, ulceration and secondary infection may occur. There is no systemic involvement or involvement of the bones and the general health remains good.

Recent reports in the literature,⁴⁰⁻⁴² however, have referred to the protean nature of the infection and to the difficulty of making a clinical diagnosis before a long-standing infection brings about the typical verrucous appearance of the lesion. Also, the diagnosis may not be readily apparent if lesions occur

in areas of the body other than on the feet, such as, the hand,⁴³⁻⁴⁶ the arm,⁴⁷⁻⁴⁹ the face,^{40, 50} the neck⁵¹ and the buttock.⁵²

Diagnosis should be made by laboratory examination of pus, crusts or biopsy sections in which the unmistakable dark-brown splitting bodies of the fungus are found. Since the different fungi (*Hormodendrum pedrosoi*, *H. compactum* and *Phialophora verrucosa*) known to produce this disease appear identical in tissue, cultures on Sabouraud's glucose agar should be made to determine exactly the fungus responsible for a given case.

There is no general agreement on the nomenclature for these fungi.^{42, 53, 54} The various spore types produced by the single species *H. pedrosoi* in culture have allowed this fungus to be placed in numerous genera according to the emphasis placed on a given spore type.

Treatment of the extensive lesion is unsatisfactory. Potassium iodide, with and without x-ray therapy, and iontophoresis⁴⁹ have been used. Early lesions, if diagnosed, should be removed by excision or destroyed by electrocoagulation.

Maduromycosis

This disease, also referred to as Madura foot or mycetoma, is produced by the greatest assortment of heterogeneous fungi. In spite of this, however, it is generally agreed that the disease is a clinical entity, and its pathology remains fairly constant regardless of the type of fungus causing the infection.

Deep-seated chronic infections of the subcutaneous tissues of the feet cause, over long periods of time, swelling and clubbing of the involved member, resulting in marked deformity. This may be accompanied by destruction of the small bones of the foot and extensive fusion of these structures. There are no systemic reactions and little pain, and the foot can be used with slight discomfort.

Scattered over the deformed foot may be seen numerous abscesses, which rupture, drain and develop into fistulas. The serosanguineous fluid from such fistulas contains the macroscopic colored grains (white, black, yellow or red) that are diagnostic when seen microscopically. Such grains are composed of a mass of broad, septate, branching hyphae containing numerous chlamydospores. The width of the hyphae and the presence of chlamydospores differentiate these grains from the granules seen in actinomycosis. In the latter disease, the granules are made up of a mass of delicate hyphae, 1 micron in diameter, which usually terminate in club-shaped swellings at the periphery of the granule.

These differences early led to the classification of mycetoma into two categories by Chalmers and Archibald⁵⁵ actinomycotic mycetoma, caused by species of Actinomycetes and maduromycosis, caused by species of higher fungi and molds. Although this classification is adhered to by many investigators,

some retain a single term, maduromycosis, since the disease is clinically and pathologically an entity regardless of the particular fungus found to be associated with a given infection

Recently, however, Symmers and Sporer⁵⁶ have reported an infection of the hand in a native American in which new histologic features were observed. Whether these findings were the result of an infection by the particular fungus responsible for their case and do not occur in infections by other hyphomycetes can be determined only by a comparative study of tissues from many cases. At the present time these authors believe that maduromycosis is a distinct disease quite different clinically, pathologically and mycologically from any other disease, particularly actinomycosis.

The various fungi that have been isolated from mycetoma are listed by Conant et al.⁵⁷ Of the 38 cases reported from the United States, only 11 can be classified as maduromycosis as proved by culture. The following fungi have been isolated: *Allescheria boydii*,⁵⁸ *Madurella americana*,⁵⁹ *M. ikedai*,⁶⁰ *M. lackawana*,⁶¹ *Aspergillus nidulans*,⁶² *Monosporium apiospermum*,^{57, 63-66} and *Torula* (?) *jeanselmei*.⁵⁶ Emmons⁶⁷ has shown that two of these fungi, *Allescheria boydii* and *M. apiospermum*, are but different phases (an ascomycetous and the imperfect stage) of a single organism.

Treatment of maduromycosis caused by the higher fungi is not satisfactory. Secondary infections by pyogenic organisms may be controlled by using sulfonamides or penicillin. The usual case, however, requires amputation.

Sporotrichosis

Whereas other fungus infections involving primarily the subcutaneous tissues are caused by a group of fungi, sporotrichosis is caused by the single organism *Sporotrichum schenckii*. Although this fungus can and does infect the entire body, producing widespread disseminated lesions, the disease is discussed among those involving the subcutaneous tissues because it is this type of infection that is encountered more frequently in the United States.

The initial lesion follows an abrasion of the skin, usually on the fingers or hands, and presents itself as a superficial necrotic ulcer that fails to heal under ordinary treatment. Lymphatics draining the area show a marked inflammation and develop multiple deep nodular subcutaneous abscesses, which usually terminate in ulceration. The intervening lymphatic vessels become thickened and cord-like in consistency. The regional lymph nodes are not involved, and the patient presents few, if any, systemic symptoms.

A clinical diagnosis of sporotrichosis is confirmed by obtaining cultures of *S. schenckii* from the ulcers or unruptured subcutaneous nodules.

This so-called "localized" lymphatic sporotrichosis is the usual type of case encountered in the United

States. Moore and Kile,⁶⁸ Forbus⁶⁹ and Singer⁷¹ have reported some of the rare disseminated cases of the disease. In Europe, however, extensive infections are the rule and any organ of the body may be affected. De Beurmann and Gougerot⁷¹ classify the clinical types as lymphatic, disseminated, epidermal, mucosal, skeletal and visceral.

Sporotrichosis may be acquired from plants or infected animals. Foerster⁷² reported cases following injury by barberry thorns and considered the disease to be an occupational hazard among farmers and horticulturists. Meyer⁷⁴ has reported infections in man following the bites of horses, dogs, hens and parrots. Anderson and Spector⁷⁶ have reported an associated sporotrichosis with rat-bite fever.

Treatment of sporotrichosis is most satisfactory with potassium iodide. Of all the fungus infections, sporotrichosis is the only one that responds specifically to this drug. Occasionally, however, an exceptional case may not respond to iodides.^{76, 77} In such cases sulfonamides may be used either orally⁷⁸ or locally.⁷⁹

(To be concluded)

CASE 31311

PRESENTATION OF CASE

A thirteen-week-old male infant was admitted to the hospital because of vomiting of blood-streaked material.

The child was the first of twins born seven weeks prematurely. This was the fifth pregnancy of the mother, and labor was short and easy. The birth weight was 3 pounds, 1 ounce. The other twin weighed 2 pounds. Both children vomited frequently, and the other child died after one week. The patient was fed human milk by gavage many times while in the hospital. In eight weeks the child was discharged, weighing 5 pounds. On the day he arrived home he vomited white curds with some dark-brown streaks. During the ensuing five weeks he vomited after almost every feeding, with frequent dark-brown streaks and material among the curds. Three days before admission, just before his evening feeding, the baby vomited a large quantity of dark-brown shiny material. He vomited again after the feeding, and the vomitus was streaked with a dark-brown substance. On the day before admission the baby was taken to a physician. While in the doctor's office the baby vomited. The vomitus, which appeared like that of the past few days, was tested by the physician and found to contain blood. On the evening before admission the baby again vomited large amounts of dark-brown material mixed with curds. While at home, he had been on a formula consisting of 16 ounces of milk and 3 tablespoonfuls of Karo, with no fruit juice or vitamin supplement. During these five weeks he had gained only 7 ounces. The mother stated that she was always careful to "bubble" the child, but despite this he would vomit about ten minutes after each feeding. The mother states that he did not vomit the entire meal. He usually had five bowel movements a day, the stools varying from yellowish and formed to greenish and liquid.

Physical examination revealed a severely undernourished and underdeveloped infant, measuring 47.5 cm. and weighing 5 pounds, 8 ounces. He ap-

peared vigorous, with a lusty cry, and seemed in no distress and fairly well hydrated. There were no skin lesions. The fontanelles were open and flat. Examination of the heart and lungs was normal. The abdomen was normal. No peristaltic waves were seen with feeding, and no masses were felt.

The temperature was normal, the pulse 110, and the respirations 40.

Examination of the blood showed a red-cell count of 3,800,000 with 8.6 gm. of hemoglobin, and a white-cell count of 16,300, with 66 neutrophils, 23 lymphocytes, 9 monocytes and 2 eosinophils. The urine was negative. The bleeding time was 6 minutes, and the clotting time 4 minutes, clot retraction was good. A tourniquet test was negative. The prothrombin time was 20 seconds (normal, 18 to 20 seconds). Vomitus and stool examinations were strongly positive for blood. A Hinton test was negative. A skin tuberculin test in a dilution of 1:100 was negative. The blood was Rh negative. The serum protein was 5.1 gm. per 100 cc. The nonprotein nitrogen, chloride, sodium and phosphorus were normal. The alkaline phosphatase was 13.7 units per 100 cc. A cephalin flocculation test was negative.

X-ray examination of the chest showed an area of increased density, apparently collapse, in the right upper lung field. There was extensive increased density in the left upper and right lower lung fields. Films of the long bones of the forearm showed no definite abnormality. A barium swallow showed the esophagus to be rather wide, but there was no demonstrable fistula between it and the trachea and no constant defects were seen. The stomach was likewise dilated, and in the distal portion there appeared a rather constant filling defect in the region of the lesser curvature. In the proximal portion of the second part of the duodenum there was a rather constant narrowing. During the examination, the barium and food content of the stomach frequently regurgitated into the esophagus. A twenty-four-hour film showed that practically all barium had passed through the duodenum.

Because of the lesion in the lungs the child was started on penicillin, 6000 units every three hours. An exploratory laparotomy was done about two weeks after admission. No duodenal obstruction or any other abnormality was found. The child withstood the operation well but continued to vomit his feedings and large amounts of coffee-ground material. He was then taken off feedings by mouth and maintained parenterally. When feedings by mouth were resumed, he again started to vomit. Attempts to stop the vomiting with sedation and with atropine were unsuccessful. Thickening of the formula was likewise not helpful. The child went downhill in spite of supportive treatment and died two weeks after the operation.

DIFFERENTIAL DIAGNOSIS

DR. SIDNEY FARBER * The patient was one of twins. The sibling weighing 2 pounds and dying after one week, with a story of vomiting, might have died because of a congenital malformation. Possibly there was infection or hemorrhage. Hemorrhage in general is the most frequent single finding in premature babies who die within ten days after birth. The fact that both babies vomited may have been merely coincidental or possibly both were suffering from the same type of malformation. Savage feeding of premature babies is frequently a necessity and saves many lives. It may be the cause of ulceration of the esophagus, however, particularly when the feedings are performed by inexperienced people. Such ulceration may form the starting point for infection, which may end in bacteremia.

We might expect that this baby had evidence of curvy and rickets in addition to other disturbances of calcification of the bones characteristic of premature babies of this size. The baby's length at thirteen weeks of age was several centimeters less than that of a full-term normal baby at birth, and the weight was roughly one third to one half of the normal weight for a full-term baby of the same age.

The findings in the differential count are of interest but give no specific information concerning a definite diagnosis. I am not familiar with the type of tourniquet test performed on premature babies of this size, but apparently there was no unusual bleeding into the skin after this was done. The tuberculin test is usually done in a dilution of 1:1000, which is not sufficient to exclude tuberculosis. Someone must have thought of that diagnosis perhaps a tuberculous ulcer of the stomach, and a test in a dilution of 1:100 was carried out before this lead was abandoned. Determination of the Rh factor is part of every routine study of the blood. I am not familiar with any disease associated with Rh blood incompatibility that would manifest itself at the age of eight to thirteen weeks, with bleeding for so many weeks thereafter. The serum protein was below normal but within the range of premature babies of this size. Occasionally with bleeding in the gastrointestinal tract the nonprotein nitrogen is increased, but here it was within normal range.

I am not familiar with the value of information derived from a cephalin flocculation test in a premature baby of this age. Let us take it as it is stated—negative. I do not believe that excludes liver disease.

From the x-ray examination we may exclude obvious rickets, scurvy and any of the important abnormalities of the skeleton associated with prematurity. The report states that the esophagus was wide, it does not say "dilated." It certainly appears to be wider than normal on these films.

*Assistant professor of pathology Harvard Medical School pathologist, Children's Hospital Boston

I assume that the fistula which was looked for was one that might have been acquired secondary to the aspiration of a foreign body, a pin or something of that kind, a congenital tracheoesophageal fistula would not be thought of at this age. May we hear from the roentgenologist?

DR. MILFORD D. SCHULZ The esophagus is wide, and there are numerous defects within it, which appear to be gas bubbles. I do not see the defect along the lesser curvature of the stomach, mentioned in the protocol. The fluoroscopist must have seen it, unless it is this area on the spot films. Again the constant narrowing of the duodenum apparently was a fluoroscopic observation.

DR. FARBER You see no evidence of duplication of the esophagus or any mass pressing against it?

DR. SCHULZ No, nor of barium in the lungs. The films of the chest are essentially as mentioned in the protocol, and I do not believe that I can add anything.

DR. FARBER I am afraid that I can say nothing more concerning the films. We have to rely on the evidence from fluoroscopy that there was a true filling defect in the lesser curvature and duodenum since these findings are not present on the films. The consolidation in the right upper lung field, with a story of vomiting, is perhaps best explained by aspiration of vomitus, which often occurs in a premature baby, but before seeing the x-ray films I suspected that a mass attached to the esophagus compressing the lung might have been present.

It must have been decided at the time of exploration that the story was not simply that of vomiting or blood streaking associated with any of the ordinary diseases of the hematopoietic system. There must have been a suspicion that an organic lesion would be found.

We have a problem here, then, which is unusual—that of vomiting of five weeks' duration before admission and of four weeks' duration after admission, with blood streaking of the vomitus in a small prematurely born infant who had gained little weight since birth. There are several possibilities that should be considered before a definite diagnosis is attempted.

Foreign body, to take the least likely possibility, is fairly frequent in children between one and two years but is relatively rare in small babies of this size, unless some extraordinary accident occurs, such as the swallowing of a safety pin or something of that kind. Foreign bodies may cause definite ulceration, particularly if they are sharp. I recall a child who swallowed a piece of artificial denture immersed in nitric acid and developed a duodenal ulcer, which was cured surgically.

Next in line of possibility are a combination of defects associated with the pancreas and an ulcer of the duodenal surface. An annular pancreas causing constriction of the duodenum can give a picture

like that described, but it would not account for the filling defect in the lesser curvature. We would have to assume that there was an ulcer of the mucosa of the duodenum or stomach, or both, if we were to give one diagnosis. There are occasional cases of annular pancreas associated with malformation of the portal region, so that portal obstruction is caused and a Banti type of obstruction is produced, with esophageal varices or varices in the stomach. This combination of circumstances is a possible explanation. These diagnoses are unlikely.

Another remote possibility, which we have encountered, is a congenital Eck's fistula associated with portal obstruction and, again, esophageal varices to account for the bleeding. Adhesions associated with malformation of the portal system might have caused the duodenal obstruction. But we are left without an explanation for the defect in the stomach.

More probable are two explanations. The first is that he had duplication of the intestinal tract, probably in several locations. This may occur in one area, or there may be six or seven along the course of the intestinal tract. There is no evidence of duplication of the esophagus, nor evidence in these films of duplication of the stomach compressing the lesser curvature or the duodenum. The x-ray studies would have disclosed such duplication, had it been there. Without evidence, however, I can do no more than mention it. Duplication of the intestinal tract may cause constriction, and there may be hemorrhage over a long period of time because of interference to the blood supply of the duodenum or stomach by the duplication, which receives its blood supply from the same source as the adjacent bowel.

The second probable explanation, and perhaps the most logical one, would account for the bleeding, either a tumor or ulcer in the stomach or duodenum. Tumors of the gastrointestinal tract in infants and children are extraordinarily rare. It might be of interest to mention that Dr J. Hawkins¹ has found that tumors of the brain in children as compared with those in adults occur in a ratio of 1:8, tumors of the kidney and adrenal gland in a ratio of 1:14, and carcinoma of the stomach and duodenum in a ratio of 1:10,000. Thus, tumors of the stomach and duodenum are rare. The only tumor that I should like to mention is a hemangioendothelioma or hemangioma, which may infiltrate the wall of the stomach or duodenum and may be found in the lower portion of the esophagus. These can bleed regularly and can be responsible for this kind of blood-streaked vomitus.

Our problem here is to find a lesion that caused irritability of the stomach, because the stomach expelled food a few minutes after eating and also caused actual bleeding. The final possibility, therefore, is duodenal ulcer or a combination of duodenal and gastric ulcers. These are more frequent in infancy and childhood than is generally recognized. They may occur in the first or second part of the

duodenum or in the pyloric end of the stomach. We have to choose a lesion that not only caused vomiting and bleeding but could not be found at operation. The lesion likeliest to hide itself in a patient of this age is an ulcer or, probably in this case if we take the defect in the lesser curvature of the stomach seriously, two ulcers. Ulcers in young infants of this age are sometimes multiple. If these ulcers are small and are located in the first portion of the duodenum, on the posterior wall or on the medial surface, — the so-called "silent" area of the duodenum, — they may not be readily found at exploration and may be found only with some difficulty at autopsy, when the entire specimen is removed and careful dissection is made posteriorly. Such ulcers usually do not cause bleeding for so long a period of time as we have heard about here. This represents an unusual history for ulcer of the duodenum or of the stomach. In infants or children the story of bleeding is usually a very direct one and death occurs in most cases within twenty-four or forty-eight hours after the onset of hematemesis.

Either a hemangioma of the stomach or duodenum or an ulcer could have been present and yet not have been seen at operation. Therefore in order of probability my diagnoses are question of duodenal or gastric ulcer and question of hemangioma of the duodenum or stomach, perhaps with infiltration of the esophagus. All other possibilities that I mentioned would have to be considered and could not be excluded, nor could their presence be included in any way by the evidence that we have. So far as the lungs are concerned, probably the child had an aspiration pneumonia, the aspirated vomitus and blood first causing atelectasis and then an aspiration pneumonia, with finally a bacterial pneumonia probably superimposed on that.

DR ALLAN M. BUTLER: One thing in the story intrigues me, namely, the nature of the vomitus. The baby was vomiting blood-streaked material and coffee-grounds material with curds. Was there any bile in the vomitus? This might help in determining whether the difficulty was above or below the stomach. The only important feature of the x-ray films is the esophagus, and I should like to ask Dr. Schulz just how impressive the widening is.

DR SCHULZ: The esophagus is somewhat wider than it usually is in youngsters of that age, but I do not know how wide it is in an infant who is vomiting as repeatedly as this child was. There is no gas in the small bowel beyond the duodenum, and none in the colon.

DR BUTLER: The description of the vomitus makes me believe that the lesion was high.

DR NATHAN TALBOT: In postulating an ulcer in the gastrointestinal tract did Dr. Farber assume an associated lesion elsewhere, or would he be surprised to find associated lesions?

DR FARBER: Ulcers in infancy and childhood are usually not associated with changes in other areas.

ushing-Rokitansky ulcers, which are frequently found in the fundus and cardiac end of the stomach, and are either agonal or extremely acute

DR S E THEODORE Was this patient studied for hiatal hernia?

DR FARBER I excluded that in considering the possible diagnosis on the basis of the x-ray findings and surgical exploration. In one or both the evidence should have been found

CLINICAL DIAGNOSIS

Intestinal obstruction due to congenital malformation

DR FARBER'S DIAGNOSES

Duodenal or gastric ulcer?

Hemangioma of duodenum or stomach?

Aspiration pneumonia

ANATOMICAL DIAGNOSES

Esophageal ulcer, traumatic (gavage tube)

Aspiration pneumonia, with multiple pulmonary abscesses

PATHOLOGICAL DISCUSSION

DR BENJAMIN CASTLEMAN The autopsy on this child showed an ulceration measuring about 1.5 cm in length in the lower third of the esophagus about 1 cm above the cardiac orifice. It had eroded the epithelium, and its base was red and granular. We found no other abnormalities in the entire gastrointestinal tract. Microscopically the base of the ulcer was composed of active granulation tissue with well marked capillary proliferation, which suggested that this had been present for quite a while. The right upper and the left middle lobes of the lung contained numerous abscesses filled with polymorphonuclears, and surrounding these were large numbers of monocytes filled with fat. These were beautifully demonstrated in preparations stained with scharlach R. There were also fairly extensive areas of pneumonia around the abscesses.

I believe that we can relate the entire case to the use of the gavage tube before the patient entered this hospital. We inquired and tried to find out how often the gavage tube was used and how long it had been kept down. We could not get the exact information, but apparently it was used many times and was kept down for varying lengths of time. The pulmonary lesions were almost certainly due to aspiration of the vomitus, which must have been mostly milk. It is also possible that at times some of the food fed by the gavage tube slipped down the larynx. This case then is an example of just what can occur as a result of improper use of the gavage tube in premature infants, as stated by Dr Farber in his opening remarks.

DR FARBER I had intended to mention that a few years ago Rector and Connerly² studied the incidence of gastric mucosa in the esophagus, find-

ing it in about 8 per cent of 1000 infants and children. They raised the question of the relation of such mucosa to the formation of ulcers of the esophagus. In this case I do not believe that we have to rely on that explanation.

DR CASTLEMAN This ulcer did not have the fibrinoid base characteristic of a peptic ulcer. It was of good size. I believe that it can be wholly explained on the basis of the gavage tube. Have you not seen ulcers of the esophagus as a result of gavage feeding?

DR FARBER Yes, but never one with a history of bleeding so long as this. This case is truly unique.

CASE 31312

PRESENTATION OF CASE

A thirty-two-year-old woman was admitted to the hospital complaining of severe headaches accompanied by nausea and vomiting.

Nine months before admission the patient had become pregnant, and at about the same time she had noted malaise, anorexia and attacks of nausea. She also complained of occasional mild headaches. Ten weeks before admission the headaches became severer and more frequent. Two weeks later, nausea and vomiting appeared and persisted. The patient was hospitalized for a week and showed some improvement following the administration of intravenous fluids and plasma. Four weeks before admission she was again hospitalized, and two weeks later underwent a cesarean section, before the spontaneous onset of labor, because of a contracted pelvis. After this operation the vomiting persisted and became progressively severer. The patient had worn glasses several years for astigmatism. During the month before admission, her vision failed rapidly, so that on admission she could not read but could still distinguish faces. During this period the patient occasionally acted strangely and at times was abnormally moody and sleepy. She had had no convulsions or deafness, but the right side of her body was consistently weak during the two weeks before admission. She had difficulty in naming familiar objects, and there was no other disturbance of speech.

The patient had previously been in good health. About four years before admission she went through a pregnancy without evidence of toxemia, being delivered of a normal, full-term child by cesarean section. Ten years before admission she had complained of vomiting and weight loss for about three months, there was no jaundice, but some abdominal pain.

Physical examination revealed a poorly developed

and nourished woman. The lips and skin were dry. The breasts were enlarged, tender and lactating. The left axillary lymph nodes were tender. The heart and lungs were normal. The abdomen was soft, and no masses were palpable.

The patient was euphonic, and speech was indistinct. Her voice was weak, she lost interest rapidly and had a small range of ideas and a poor memory. The pupils were equal, each measuring 5 mm in diameter, the left was irregular and did not react to light. There were no specific weaknesses of the extraocular muscles, but eye movements were not carried so far to the left as to the right. The patient stated that she had had intermittent diplopia, worse when she was not looking straight ahead. There was papilledema of 3 diopters on the right, and 5 diopters on the left. Visual acuity was greatly diminished. The visual fields were apparently normal. A right facial paresis was present. Auditory acuity was slightly diminished on the left. The neck was slightly stiff, and a Kernig sign was present. Motor weakness was generalized, more marked on the right than on the left. The tendon reflexes were bilaterally hyperactive, particularly on the right, and there was ankle clonus bilaterally, more marked on the right than on the left. The abdominal reflexes were absent. The plantar reflex response was extensor on both sides.

The temperature was 99.2°F, the pulse 100, and the respirations 20. The blood pressure was 110 systolic, 55 diastolic.

The urine on admission contained no sugar but gave a ++ test for acetone, the sediment contained 10 white cells per high-power field. The red-cell count was 3,700,000, and the white-cell count 12,000, the hemoglobin was 11.5 gm per 100 cc.

A lateral x-ray film of the skull showed a calcified plaque in the parietal region. On ventriculography, the fluid in the right ventricle was under increased pressure, which rapidly fell to normal. A large mass appeared to be present in the left frontal region, this markedly depressed the left anterior horn and forced the ventricles, including the third, to the right. The ventricles were not distended. Electroencephalography revealed focal disturbance, greatest in the left frontal region.

A left frontoparietal craniotomy was done on the first hospital day, and 65 cc of thick, brown fluid was aspirated by needle. The patient's immediate postoperative condition was poor. She was unresponsive, with fixed pupils and ankle clonus. All other reflexes were absent. A lumbar puncture revealed slightly bloody spinal fluid under an initial pressure equivalent to 450 mm of water, the final pressure was 100 mm. The blood pressure remained almost constant at 90 systolic, 60 diastolic. The pulse varied from 140 to 160, and the temperature from 100 to 105°F. Although she received 1500 cc of whole blood and 1500 cc of glucose in water, she remained unconscious. A second lumbar puncture

also yielded bloody fluid under an initial pressure equivalent to 400 mm of water, after slow withdrawal of 10 cc the pressure fell to 180 mm.

Late on the first postoperative day the respirations became markedly slowed. An hour later respirations ceased, with persistence of the heart beat for a short time longer.

DIFFERENTIAL DIAGNOSIS

DR JOST MICHELSEN. It is not difficult to decide that this patient had a space-occupying lesion. There were characteristic manifestations of increased intracranial pressure, such as severe headache, nausea and vomiting, failing vision, drowsiness and papilledema. We are also given the localization of the lesion. It involved the left side of the brain, producing weakness of the right side of the body and probably also the disturbances of the oculomotor mechanism by damage to Area 8. The ventriculogram showed a mass in the left frontal region; the electroencephalographic studies were consistent with a lesion there, and I presume that the fluid-containing cavity was found in the same area.

Reviewing briefly some of the signs, I am not certain whether the anomia was actually found on examination or whether some of the patient's complaints were interpreted as an amnesic aphasia. We are not told, either, whether she was right or left handed. If her dominant hemisphere was on the left side, a frontal lesion should have produced a defect in word formation rather than anomia.

Another observation deserves some comment. It is said that the left pupil was irregular and did not react to light and that both pupils were fairly wide and equal. The irregularity may have been due to an old lesion of the iris. The absence of the light reaction probably was the result of severe damage to the left optic nerve, in other words, the patient was blind in the left eye. The fact that the papilledema on the left side was 5 diopters — as compared with 3 diopters on the right side — is certainly suggestive. One would be more certain with regard to this point if the findings on testing the consensual light reaction were known and recorded.

It is obvious that the most important question to be answered in this case is that concerning the character of the mass. If we attempt to make a preoperative diagnosis in the average case we take into account the age of the patient, the history, the situation of the lesion and the radiographic appearance of the skull. In this case we are also informed about some of the findings at operation. The surgeon aspirated 65 cc of thick, brown fluid, which indicates that there was a large cyst, and we shall have to form an opinion concerning the type of the cyst.

The history contains quite a few details of the patient's pregnancy, and this case was announced on the bulletin board as one with cerebral symptoms following pregnancy. Considering all the evidence

ffered, I do not hesitate to disregard the apparent toxemia during the early course of her pregnancy as an etiologic factor. I believe that the appearance of symptoms during her pregnancy — as in some other cases that we have seen — was entirely incidental and perhaps quite misleading to her family physician. Occasionally in a slowly growing tumor exacerbation of manifestations is observed during pregnancy. Dr B Brouwer,* of Amsterdam, observed a patient who, during her sixth pregnancy, developed a bitemporal hemianopsia. It was thought that this was a complication of her pregnancy. Indeed, after delivery her visual fields became normal. With her seventh, eighth and ninth pregnancies she also had transient bitemporal hemianopsia. After delivery of her tenth child, however, the hemianopsia persisted. She then developed headaches, and it turned out that she had a parasellar meningioma.

It is also hardly conceivable that the patient had a parasitic cyst. There was no evidence of cysts elsewhere in the body. There was no eosinophilia. The character of the aspirated fluid was different from that found in a parasitic cyst.

A bacterial infection is quite unlikely, although we are told that the neck was slightly stiff and that a Kernig sign was present. There was no adjacent or distant source of infection so far as we know.

Therefore, we must consider some of the brain tumors in which cyst formation occurs. At this point I should like to ask Dr Schulz to say a few words about the calcification in the occipital region.

DR MILFORD D SCHULZ. The calcification is in the occipital region on the right. It lies fairly close to the midline but scarcely closely enough to the midline to be outside the occipital lobe, it seems to lie above the tentorium.

DR MICHELSEN. Is it quite unlikely that the calcification has anything to do with the mass in the frontal area?

DR SCHULZ. Yes. Certainly there is a considerable distance between the two.

The anteroposterior film shows the deformation and displacement of the frontal horns. The left one is pushed down under the tentorium, and to the right, and the right one and third ventricle are displaced to the right.

DR MICHELSEN. Do you consider that the cyst represents a second lesion?

DR SCHULZ. I think that there were two separate lesions.

DR MICHELSEN. I shall rule out an astrocytoma because of the rapid course of the patient's disease, the absence of epileptic seizures and the character of the fluid. A craniopharyngioma would not have occupied the left frontal lobe, depressing the anterior horn of the lateral ventricle — these tumors arise from below in the suprasellar region. Furthermore, the clinical symptomatology in this case is against such a diagnosis.

*Brouwer B. Personal communication.

A glioblastoma multiforme is a fair possibility. These tumors grow rapidly. The occurrence of hemorrhagic extravasations and necrosis is frequent and would account for the brown color and the consistence of the cystic fluid. We also ought to consider metastatic carcinoma, although there is little evidence in the story to support this diagnosis, except that the patient was in poor shape and had acetone in the urine as an indicator of malnutrition.

There is one other type of tumor, however, in which thick, brown fluid is fairly characteristic. Was a microscopic examination done on the fluid?

DR CHARLES S KUBIK. That was done, and there were large vacuolated cells that probably contained fat. Such cells are present in the cystic fluid of various kinds of tumors. There were no cholesterol crystals.

DR MICHELSEN. Dr Kubik has anticipated my thought. I had in mind a dermoid cyst. These tumors are rare. They are usually located in the midline, basally, but they may occur in the different lobes of the forebrain. At times they are multiple. They grow at a very slow rate and may attain a considerable size before resulting in symptoms.

Now let us search for the cause of death. This patient was a nearly hopeless surgical problem from the onset. Her general condition and nutrition were poor, as mentioned before. She had bilateral pyramidal-tract disturbances, which I have omitted from the discussion so far. They, and possibly also the rigidity of the neck and the Kernig sign, seem to indicate that there was some tentorial herniation preoperatively as a result of markedly increased intracranial pressure. This condition apparently was not relieved by the removal of the cyst fluid, indeed it progressed, and the two postoperative lumbar punctures certainly did not help the situation. The patient developed hyperthermia and respiratory failure.

In conclusion, I should say that this patient had a brain tumor and that during the last few days of life a tentorial pressure cone occurred, which resulted in death. The tumor may have been a malignant, necrotic, hemorrhagic glioma, a dermoid cyst or possibly a metastatic carcinoma. I am prepared to hear that it was none of the three.

DR BENJAMIN CASTLEMAN. Would you like to say a word about this patient's pregnancy, Dr Newell?

DR JOHN L NEWELL. I do not see how the tumor could have been associated in any way with the pregnancy, which was a full-term cesarean delivery. The vomiting and headache were probably passed off as being due to the pregnancy, and this was undoubtedly misleading.

CLINICAL DIAGNOSES

Brain tumor
Respiratory failure

DR MICHELSEN'S DIAGNOSES

Brain tumor (glioma, dermoid cyst or metastatic carcinoma)
Tentorial pressure cone

ANATOMICAL DIAGNOSES

Adenocarcinoma of lung, with metastases to bronchial lymph nodes and brain.
Tentorial pressure cone, with cerebral infarction.

PATHOLOGICAL DISCUSSION

DR CASTLEMAN Before I tell you what was found at autopsy perhaps Dr Kubik would like to tell what was found in the brain grossly

DR KUBIK In the left frontal region there was a tumor a large part of which was taken up by a cystic cavity measuring 2.5 cm in diameter and containing a small amount of coagulated brownish fluid. The cavity was naturally much larger before the cyst was drained at operation. There was an exceedingly large temporal pressure cone on the left side, and a smaller one on the right, with resulting compression of the midbrain. The aqueduct was flattened to the point of obstruction. There was a small hemorrhage in the midbrain in the region of the third-nerve nuclei. Either the compression of the midbrain or the implication of the third nerves might have accounted for the diplopia and the dilated fixed pupils. There was also extensive, recent, hemorrhagic necrosis of a large part of the left cerebral hemisphere. Such necrosis, resembling hemorrhagic infarction, is not infrequently ob-

served with a temporal pressure cone, but the infarcted region is usually the one supplied by the posterior cerebral artery, presumably because this artery is compressed by the inner edge of the tentorium. I do not know how to account for infarction in this case, because the infarcted regions are supplied by both the posterior and middle cerebral arteries. There was also a large cerebral pressure cone, which no doubt accounted for the respiratory paralysis. It is reasonable to suppose that both the temporal and the cerebellar pressure cones were made worse by the lumbar punctures.

DR CASTLEMAN The tumor microscopically was a metastatic carcinoma. The primary source was in the right upper lobe bronchus. Unfortunately an x-ray film of the chest was not taken. There was an ulcerating tumor in the bronchus, with extension to the surrounding parenchyma of the lung and with metastases to the bronchial lymph nodes.

The uterus was enlarged. It had not completely involuted, and in the endometrium were shaggy clots, which allowed us to toy with the idea, based on the gross findings, that it was a chorionepithelioma with metastases to the lung and brain. Histologically, however, the tumor was an extremely rapidly growing adenocarcinoma and not a chorionepithelioma.

The pregnancy may well have made the tumor grow much faster, and this rapid growth of the tumor cells may have accounted for the fact that the tumor was cystic, that is, it had broken down because it had outgrown its blood supply. The bronchial lymph nodes were also necrotic.

PHYSICAL FITNESS AFTER THE WAR

THE ineligibility for military service of over 30 per cent of the men examined under Selective Service is one of the outstanding health facts uncovered by the war, and those who have used the war as a sounding board for their prewar convictions are already exploiting this fact by resolving in public, as usual, that such a thing must never happen again. To say, on the other hand, that physical standards for large bodies of men were never before so high as they are in our armed forces is merely to state the obvious. So far as the medical profession is concerned, it has a definite obligation to give this matter its attention, to formulate its opinion and to raise its voice in the current political discussion.

How can we reduce to a minimum the physical defects of another generation? There are, to begin with, certain obstacles of an emotional nature with which we shall continue to contend, and we must also recognize the biologic fact that no seed is of uniformly high quality. Nurserymen and raisers of livestock know that nature with its infinite variety, produces, even with the best seed and stock, a considerable percentage of imperfectly formed specimens — stunted plants or runts. The nurseryman and farmer cull these from their crop or herd, being under no compulsion to raise them, although of course, they could, with time and patience, nurse many of them to maturity. We have no such freedom of action in human nurseries. Ours is a civilization in which we strive for the protection and survival of the unfit.

The medical profession's major activities have for years been concerned with such protection and survival, and in view of its accomplishments and its support by the public it is today actually responsible for the survival of many of those who have been found ineligible for military service, in other words, we have reversed the philosophy and the practice of the ancient Spartans. We must also recognize that, in many places, legal and political impediments have been placed in the way of parents who may have biologic as well as economic reasons for controlling the birth of their offspring. These are the obstacles — paradoxical and perhaps insurmountable — with which our civilization contends and will contend at the close of the war. In view of them the conditions revealed by the statistics of the Selective Service and induction boards are not at all amazing, they are only what might have been expected, although many of us have been startled by the fact in this period of national crisis.

The greatest difficulty with which we are confronted in attempting to reduce the numbers of the physically unfit in a democracy is the freedom of the individual to neglect himself. It would be a good freedom to abolish if such a thing were justifiable, and the medical profession should support any reasonable steps likely to promote physical fitness.

At the present time there are two political rings into which the profession can throw its hat. The first is the constructive health-education program

that has been adopted by many cities and towns outside Boston, largely owing to the efforts of the Massachusetts Department of Public Health and Department of Education, and that is recommended by the Strayer Report as a procedure that might well be adopted in the schools of Boston. This is something that doctors can approach locally, where they can tactfully secure what intimate knowledge of existing conditions is necessary to initiate a reform, good medical leadership of this type being seldom challenged. The other political ring is that which encircles those who are now debating peacetime military training. Here will be found a sharp cleavage of opinion — one in which the clergyman, the professional soldier, the statesman, the businessman, the educator and many other intelligent people are divided among themselves. This being so, and in view of the biologic and psychologic facts that every doctor knows, it is the duty of organized medicine and of each individual physician to throw themselves vigorously into the debate in favor of peacetime conscription.

Even in wartime the Army has rehabilitated close to two million men, in peacetime it could unequivocally eliminate many of the correctible defects that are now neglected by parents, school authorities and individuals. Universal military training in peacetime would do more to improve the physical fitness of the Nation's young men than any other method that could be devised. There should be no division of opinion in the medical profession on this issue.

SPREAD OF STREPTOCOCCAL INFECTIONS

DURING World War I, hemolytic streptococcus infections were the most serious and the most frequent complications of measles and influenza, as well as of wounds, and they probably accounted for a great many of the deaths ascribed to these conditions in the United States Army. The rapid spread of such infections in Army hospital wards was the subject of numerous studies at that time. The recognition of specific groups and types of hemolytic streptococci during the last decade has given epidemiologists a highly useful tool whereby they can trace the sources and spread of such infections with

reasonable assurance and accuracy. Although hemolytic streptococcus infections are not nearly so prevalent now, either in civilian or in military populations, as they were during the first world war, they still constitute an important problem at certain Army and Navy installations. Hence, various groups of workers have been engaged in studying these infections. Among them, the Commission on Air-Borne Infections has obtained useful information concerning the quantitative aspects of the transmission of hemolytic streptococci in Army hospital wards.

Hamburger,¹ in a report of some of these studies, re-emphasized certain of the known facts and brought out some new and useful ones that are essential for the control of infections with these organisms. He found, for example, that gross infections by hemolytic streptococci on open wards may spread rapidly when only as few as one or two carriers are originally present. On the other hand, as many as 50 per cent of the patients on a ward may harbor Group A streptococci in their throats without cross infection's occurring in any of the others. On the average, the carrier rate for a specific type known during the same season to be invasive may be as high as 19 per cent without the occurrence of cross infection. "Subclinical cross infection," that is, a spread of carriers or of cases of mild infection by hemolytic streptococci, was quite frequent.

As already indicated, outbreaks of measles have been known to encourage the spread of hemolytic streptococci and to give rise to serious respiratory complications with these organisms. During the present war, cases of German measles have been unusually prevalent. This disease is ordinarily considered to be a mild one of little or no consequence. In the present investigations, however, Hamburger found that patients recovering from German measles share the well recognized susceptibility of those with measles to streptococcal infections.

In the course of tracing the origin of cross infections with streptococci, emphasis was placed on the importance of typing the streptococci before a member of the hospital personnel who is a carrier can be incriminated as the source of the infection. Actual typing under such conditions may indicate that an entirely different strain is responsible for

the cross infection than the one or ones found in the carriers among the personnel. This may also be of importance in surgical practice, where the spread of streptococcal wound infections is often ascribed to a surgeon or an operating room nurse who happens to be a carrier. Such persons are often kept from the operating rooms when they are not the ones responsible for the cross infections.

Attempts were also made to determine to what extent streptococcus carriers may disseminate their strains.² This was done by comparing the results of throat cultures with quantitative estimations of the numbers of organisms in the saliva, the latter being presumed to be the origin of droplets from which the organisms get into the air and dust. It was found that a person with a positive throat culture may or may not have the same organism in the saliva. In cases of active sore throat, to be sure, over 80 per cent of the specimens of saliva contained the same strains of streptococci as were found in the throat cultures but the rest had no streptococci in the saliva. The relation of the positive throat and salivary cultures in any patient varied from day to day. In about half the cases the number of hemolytic streptococci in the saliva diminished in successive samples, usually gradually but sometimes quite abruptly. In about a fourth of the cases the results of repeated cultures were the same over a period of weeks, about half of these having positive and the other half negative cultures of the saliva. Cases of scarlet fever and those of pharyngitis or tonsillitis without a rash behaved alike with respect to the number of streptococci in the saliva. Tonsillectomized patients tended to carry fewer streptococci in the saliva, and for shorter periods, as compared with those who had tonsils. None of these findings had any relation to the type of the streptococci. Interestingly enough, treatment with sulfonamides did not permanently eliminate or decrease the numbers of hemolytic streptococci either in the throat or in the saliva.

Since the commission was interested primarily in air-borne infections they made extensive studies of hemolytic streptococci in the air, floor dust and bedclothes in the hospital wards.³ The great difficulty of proving that cross infections in a ward are truly air borne, and not spread by contact, was emphasized.

One case was noted of a technician in whom there was a strong suspicion of accidental air-borne infection from prolonged exposure at a distance from patients. This technician was engaged in taking air samples and it was calculated that the total dose that she inspired was about 13,000 organisms.

Many known epidemiologic facts about hemolytic streptococcus infection in the environment were confirmed by accurate methods. It was found, for example that the rise and fall in the number of streptococci in scarlet-fever and sore-throat wards paralleled the fluctuations in the total numbers of bacteria in the air although the streptococci constituted a small part of the total. Most of the other organisms were saprophytes and, therefore probably arose from dust and bedclothes, which contain tremendous numbers of bacteria. Pockets of high concentrations of hemolytic streptococci were associated with high concentrations of saprophytes during periods of sweeping or bedmaking. The largest numbers of streptococci were found in the air dust and in the bedclothes nearest those patients who actually eliminated the largest number of streptococci.

On the basis of their observations, the members of the commission were not able to determine accurately the exact role of air-borne and dust-borne infections. They suggested however, that the control of air-borne streptococci in hospital wards may be largely a question of controlling the secondary reservoirs of these organisms in the dust and bedlinens. The results of studies in which this was attempted seem to indicate that such control is feasible. The maximum reductions in air-borne streptococci were observed when oiling of the bedclothes and floors was used in conjunction with glycol vapor.⁴

COMMENT

Only two cases of anterior poliomyelitis were recorded in June. It should be pointed out, however, that no conclusions can be drawn from this fact with reference to the likelihood of an outbreak later in the season. Even the July figures are not always an accurate indication of what to expect.

Lobar pneumonia showed a very low incidence — the lowest for June since 1922.

Mumps was at the lowest point of this year but was, nevertheless, at the highest level of any June on record.

Diphtheria was still higher than in recent years. Only once since 1937 has June shown as many as 14 cases.

Only once before have more than 18 cases of Salmonella infections been reported in June.

GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Anterior poliomyelitis was reported from Haverhill, 1, Holyoke, 1, total, 2.

Diphtheria was reported from Boston, 3, New Bedford, 2, Newton, 1, Norwood, 1, Somerville, 5, Taunton, 1, Worcester, 1, total, 14.

Dysentery, amebic, was reported from Regional Hospital, Waltham, 1, Camp Edwards, 2, total, 3.

Dysentery, bacillary, was reported from Wrentham, 1, total, 1.

Malaria was reported from Arlington, 1, Boston, 3, Camp Edwards, 17, Fort Devens, 55, Gloucester, 1, Lawrence, 1, Norwood, 1, Somerville, 1, Springfield, 1, Waltham Regional Hospital, 11, total, 92.

Meningitis, meningococcal, was reported from Attleboro, 1, Boston, 6, Dedham, 1, Fall River, 1, Holyoke, 2, Ipswich, 1, Lynn, 1, Malden, 1, Newton, 1, Norwood, 1, Quincy, 1, Randolph, 1, Topsfield, 1, total, 19.

Meningitis, Pfeiffer-bacillus, was reported from Arlington, 1, Cambridge, 1, total, 2.

Meningitis, pneumococcal, was reported from Boston, 1, total, 3.

Meningitis, streptococcal, was reported from Boston, 1, Worcester, 1, total, 2.

Meningitis, other forms, was reported from Boston, 2, total, 2.

Meningitis, undetermined, was reported from Brookline, 1, Springfield, 2, total, 3.

Salmonella infections were reported from Boston, 3, Cambridge, 1, Haverhill, 1, Malden, 1, Marblehead, 6, Newton, 2, Northampton, 1, Salem, 2, Wellesley, 1, total, 18.

Septic sore throat was reported from Boston, 4, Easton, 1, Haverhill, 1, Lynn, 6, Medford, 1, Sharon, 1, Williamstown, 3, total, 20.

Typhoid fever was reported from Lowell, 1, New Bedford, 1, total, 2.

Undulant fever was reported from Adams, 1, Dighton, 1, Sheffield, 1, Waltham, 1, West Boylston, 1, Williamstown, 1, total, 6.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

A Textbook on Pathology of Labor, the Puerperium and the Newborn. By Charles O. McCormick, M.D., clinical professor of obstetrics, Indiana University School of Medicine, and consulting obstetrician, William H. Coleman Hospital for Women, Indianapolis City Hospital and Sunny Side Sanatorium. 8th, cloth, 399 pp., with 191 illustrations, including 10 in color. St. Louis: The C. V. Mosby Company, 1944. \$7.50.

The author's lectures, prepared for the senior medical students at Indiana University, have served as a basis for this new work on the pathology of labor. An attempt has been made to set forth only the essentials of present-day obstetrics, purposely avoiding confusing textbook material. Special consideration has been given pelvimetry, breech extraction, placenta previa, post-partum hemorrhage, use of forceps, version and cesarean-section techniques, puerperal infection, breast pathology and asphyxia neonatorum. There are detailed descriptions of therapeutic and surgical procedures, of tubal sterilization operations and of the newer therapeutic adjuncts, such as puerperal sterilization, sulfonylamides, penicillin and stilbestrol, vitamin K, erythromycin and improved analgesia. The book is well illustrated and printed on good paper. References to medical literature have been incorporated in the text instead of placing them at the end of chapters.

Technique of the Standard Kahn Test and of Special Kahn Procedures. By Reuben L. Kahn, chief of clinical laboratories, University of Michigan Hospital. Revised and enlarged edition. 8th, paper, 52 pp., with 4 tables. Ann Arbor: University of Michigan, 1944. 25 cents.

In this revised and enlarged outline, Dr. Kahn presents the technique of the standard Kahn test with serum and spinal fluids, the interpretation of precipitation results and techniques of special procedures, with an appendix on the preparation and standardization of antigen. The pamphlet is divided into four parts, with an appendix apparatus, reagents, standard Kahn procedures, and special Kahn procedures.

Number 6

SENILE PSYCHOSIS AND PELLAGRA*

A Report of Two Cases

HERMAN ARNOLD MEYERSBURG, M D †

CHARLOTTESVILLE, VIRGINIA

SEVERAL patients with psychoses of the senile type have been observed to improve after a period of therapy with niacin, thiamine, riboflavin and substances rich in the vitamin B complex. Review of their records has shown 2 with atypical pellagra. In view of the probable relation of pellagra to the clinically observed psychoses, these cases will be reported. The number of cases observed is not sufficient to warrant a statistical analysis, but the indications are that they are not infrequent

* * *

The neuropsychiatric manifestations of pellagra in the early stages of the disorder are vague, consisting of irritability, weakness, lassitude, skeletal pains and severe malaise. As the disease advances more definite syndromes may appear—depressive states, manias, paranoid states, acute confusional states, agitated anxiety states and hallucinatory states. In the end stages, evidence of severe neurologic impairment may develop—stupor, convulsions, incontinence, impaired thermal regulation, muscular rigidity, irregular involuntary movements of the musculature, hypertonia, defective sensation and muscle paralysis. The manifestations may be solitary or occur in various combinations.¹⁻⁹

Neurohistologic studies performed on pellagrins have revealed atypical neuronal and capillary changes distributed throughout the neuraxis,¹⁰⁻¹³ especially in the cerebrum. Within the cortex the ganglion cells may lose their Nissl substance and eventually disappear. The extent of this change varies from case to case, as a rule it is most noticeable in the frontal lobes and in the hippocampus. In addition, there may be proliferation of glial tissue and of the endothelium of small vessels. In the subependymal regions the proliferative reaction may be the most noticeable.^{10, 11} Circumscribed parenchymal changes are usually associated with such vascular lesions. These reactions are to be found in a wide variety of so-called "toxic"

encephalopathies (central neuritis), as well as in pellagra.

Pellagrins with neuropsychiatric disorders have been treated successfully with niacin.¹⁻⁶ Some investigators have presented evidence that the results are more satisfactory when niacin is supplemented with other vitamins of the vitamin B group and a well balanced diet.^{2, 5, 14}

The neuropsychiatric disorders that accompany old age may be considered in two categories—those arising primarily in the brain tissue and those secondary to an impaired circulation.

The first is an involution, a natural consequence of aging. It varies in intensity from a mild forgetfulness and a tendency to reminisce to extreme confusion, disorientation and dementia. The usual occurrence is in the years beyond the eighth decade, but similar conditions are known to affect persons in earlier life. When severe, the latter group may give rise to presenile dementias. These conditions are insidious and progress slowly.^{15, 16} The pathologic alterations in the brains of patients so affected are notably a loss of neurons, neurofibrillary degeneration and the development of senile plaques or collections of amorphous deposit. Such changes are most noticeable in the frontal-lobe cortex, the Purkinje-cell layer of the cerebellum and the striatal portion of the basal ganglia.¹⁷ Often there is a wide discrepancy between the severity of the clinical disorder and the extent of the pathologic change within the brain.^{17, 18}

In the second type, the clinical disturbances are due to loss or impairment of parenchymal function as the result of impaired circulation. The syndromes produced may simulate those seen in the more advanced cases of the previous group, but oftener signs of focal lesions are present—hemiplegia, aphasia, agnosia and similar manifestations. The patients with vascular affection are more strikingly confused and disoriented than those in the other category, they have more vivid hallucinations. Lesions are likeliest to occur in the regions supplied by the middle cerebral artery and its branches. The size and extent of lesions vary from small

*From the Department of Neurology and Psychiatry (service of Dr. David C. Wilson), University of Virginia Hospital.

†Formerly resident neuropsychiatrist, University of Virginia Hospital.

ischemic foci involving the cortex alone to large infarctions affecting the whole hemisphere

Although the differences between these two groups of patients may be recognized in some cases, Critchley¹⁷ has stated, "We must admit that the distinction is more academic than practical, since in the great majority of cases the process of aging operates simultaneously on both the parenchyma and the blood vessels of the brain"

The occurrence of so-called "senile psychosis" in association with pellagra was noticed by Singer,⁸ who concluded that in these cases pellagra is only incidental. Lorenz⁹ observed a similar coincidence. He wrote

Chronic mental states largely ascribed to pellagra are those occurring late in life. A number of cases were observed showing typical senile dementia. These were all advanced in years and the occurrence of mental defects of this nature would have been expected. Likewise, a number of cases with marked peripheral arteriosclerosis showed a general mental enfeeblement such as is usually associated with sclerosis of the cerebral vessels. That these may have developed at a somewhat earlier period owing to the pellagra is not questioned. These are probably instances in which pellagra served as a precipitating factor in the development of a psychosis of the senile or vascular type

Rainsford,¹⁹ Bonhoeffer,²⁰ Bigland²¹ and McGregor²² have reported cases that could have been similarly classified. Chittick and Stotz²³ quote Tompkins as stating that of 25 patients recovering from senile psychoses, 5 had had glossitis during the early stages of hospitalization, and this finding is believed by them to have been indicative of a nutritional deficiency state. Rothschild and Sharp²⁴ and Woltman²⁵ stress the importance of adequate nutrition in maintaining cerebral function in aged persons. Robinson²⁶ describes "toxic-delirious reactions of old age" and mentions the importance of metabolic and nutritional disturbances in precipitating such reactions. Wadsworth et al²⁷ used vitamin B complex in the treatment of an unselected group of senile psychotic patients, with indifferent results. Palmer and his co-workers²⁸ reported on a group of 123 institutionalized senile psychotic patients, 30 of these recovered when given supportive therapy, which included large doses of vitamin preparations.

In neurohistologic studies of pellagra, Singer and Pollock¹² noted the occurrence of neurofibrillary ganglion-cell degeneration in some specimens, but made no mention of the ages of the patients from whom these were taken. Pearson¹³ encountered a case with a clinical picture of a senile psychosis among a group of patients in whom central neuritis was found at autopsy. Although none of these findings are conclusive, they indicate the possibility of a closer relation between some of the senile psychotic episodes and pellagra.

CASE REPORTS

CASE 1. E. D., an emaciated 55-year-old woman, was admitted to the neuropsychiatric service of the University of Virginia Hospital on September 6, 1942. Her illness had

begun late in 1929 with severe pains in the lower extremities. This was followed by progressively increasing weakness, which necessitated her remaining in bed. In addition, mental symptoms appeared, notably irritability, contrariness and emotional instability. Within several months after the onset the patient's appetite had failed and her food intake had decreased to half the usual quantity.

In the 9 succeeding years there were brief periods of partial remission, but otherwise the clinical picture remained unchanged despite medical care. In the summer of 1939 the patient became semistuporous and remained in that state for nearly a month. As a sequel to this, her intellectual function deteriorated further and her weakness increased. No further remissions occurred.

During the early part of 1942 the patient's emotional symptoms became exaggerated. On August 21, 1942, she lapsed into a stupor that persisted for 4 days. Recovery after this was very poor and the patient was hospitalized.

On admission the patient was confused, disoriented and agitated and complained of pains throughout the body. She was easily distracted, expressed paranoid and depressive ideas and prattled extensively. She had auditory and visual hallucinations of a morbidly violent character, which caused restless overactivity and often interfered with sleep. She echoed the gestures and speech of the examiner but was unable to perform skilled movements. She was moderately aphasic.

Physical examination revealed a dry skin. There were seborrheic excrescences in the nasolabial folds and macerations at the corners of the mouth. The oral and pharyngeal mucous membranes were dry and reddened. The tongue was magenta red. There were two shallow ulcers approximately 0.5 cm in diameter on the posterior wall of the pharynx. The cardiovascular and respiratory systems were not unusual. The abdomen was normal. The musculature of the extremities was wasted and tender on deep pressure. The patient was unable to arise from bed because of generalized weakness. All the tendon reflexes were hyperactive, except at the left patella. Abdominal reflexes could not be elicited. The plantar reflexes were normal. Vibratory and position senses were severely impaired, producing a stereoaesthesia. Other neurologic findings were normal.

The red-cell count was 4,030,000, and the white-cell count 6600, the hemoglobin concentration was 12 gm per 100 cc. The blood sugar concentration was 46 mg per 100 cc, and the urea concentration 46 mg. Wassermann and Kahn reactions were negative. The urine was normal. Gastric analysis showed 12 units of free acid.

At the time of admission the patient refused to eat and had to be fed by gavage. Two days following admission treatment was instituted with large doses of nicotinic acid amide, riboflavin, brewers' yeast powder and thiamine chloride. By the 6th day she was able to eat. The oral and nasolabial lesions cleared by the 7th day. The patient's mental acuity increased gradually and the bizarre patterns of thought disappeared, but the emotional lability persisted. In the early part of October treatment was supplemented with intramuscular doses of crude liver extract. During the month intellectual function improved surprisingly, but the tongue remained magenta red, and the emotional reactions immature.

The patient was discharged on October 25. During the succeeding 2 months she remained well, but shortly after Christmas she again became irritable and lost her appetite. In late January, 1943, soreness of the tongue developed and the patient sought readmission.

At the second admission, the patient complained severely of gastrointestinal discomfort. Clinical, roentgen-ray and laboratory examinations revealed no organic lesion in the stomach or bowel. After treatment with crude liver extract and brewers' yeast powder there was gradual improvement, but vague neurotic complaints persisted. At no time did the magenta-red color of the tongue disappear. Treatment was continued after discharge, and no further recurrences were noted over a 10-month period.

*The daily dosages of vitamins were as follows: nicotinic acid amide, 0.6 to 1.05 gm in divided doses by mouth; riboflavin, 0.01 to 0.02 gm by mouth; thiamine chloride, 0.050 gm parenterally and brewers' yeast powder, 15.0 gm by mouth.

†The daily dose of crude liver extract (Lederle No. 9083-291811) kindly supplied through the courtesy of Lederle Laboratories Incorporated, Pearl River, New York, was 5 cc.

‡A full scale Wechsler-Bellevue test on October 22 revealed an IQ of 125.

Comment The duration of the disease in this case was unusual since one would not expect improvement of such degree after this length of time. The late manifestations were like those of a vascular disturbance, although the earlier ones were neurasthenic. The latter disturbances, the memory defects and the confabulatory episodes resembled the Korsakoff syndrome, which may occur in either the senile psychoses or in pellagra. The episodes of stupor were similar to those described in pellagrins by Cleckley and his co-workers.³ The skin lesions were those of riboflavin deficiency, and the mucosal alterations were the combined effect of several deficiencies. The response to treatment puts this case definitely in the pellagra group.

CASE 2 R. L. B., a 78-year-old man, was admitted to the medical service of the University of Virginia Hospital on October 31, 1942. Three days preceding admission he suffered a "stroke" and as a result became irrational.

Six years prior to admission he was hospitalized for an acute otitic infection. At that time he had choreiform tremors, but these were not described further. The blood pressure was then 150/85 and the urine had a specific gravity of 1.022 and was otherwise not remarkable. At a subsequent examination in 1938, no mention was made of any tremor. From 1939 to 1942 the patient had been under the care of his family physician for hypertension. During the last-mentioned year he had been having frequent slight "strokes" that resulted in progressive impairment of locomotion and in transient confusional states. The lower extremities "felt like blocks of wood" and he could not be sure of their position. On October 24, 1942, he suddenly became confused and lost the power of speech. He refused all food and fluid, developed a fever and within a few days became completely irrational.

At the time of admission the patient was noisy, inattentive and easily distracted. His emotional reactions were labile and he was overly concerned with religious matters. Motor and sensory aphasia, echolalia, echopraxia and perseveration of responses were present. The bladder and bowels were incontinent.

On physical examination, cachexia was noticeable. The skin was dry and thickened. The conjunctivas and scleras were hyperemic. The retinal vessels were slightly narrowed. The mucous membranes of the mouth and pharynx were reddened and edematous. A few carious teeth remained in the lower jaw, the periodontal tissues were severely infected. The skin of the chest was covered with the lesions of a seborrheic dermatitis. The lungs were normal. The heart was clinically enlarged, and the rhythm was irregular owing to numerous extrasystoles. The blood pressure was 220/120. There were reducible bilateral inguinal hernias. A shallow decubitus ulcer overlay the sacrum. There was extensive peripheral arteriosclerosis. There were uncontrolled irregular movements of the extremities. The musculature was weak and wasted. All the tendon reflexes were hyperactive, especially on the right side. The abdominal reflexes were easily fatigued. The right plantar reflex was extensor and the left one normal. The special senses could not be evaluated, but otherwise the functions of the cranial nerves appeared normal. General sensibility was such that only strong thermal and painful stimuli evoked any responses. Sucking reflexes could be elicited, and a grasping response was present in the right hand.

The red-cell count was 5,300,000 and the white-cell count 12,000. There was a hemoglobin concentration of 16.5 gm per 100 cc, and a blood urea concentration of 86 mg. The Wassermann reaction was negative. The plasma carbon dioxide combining power was 58.6 vol per cent. The urine contained a small amount of albumin and an occasional leukocyte was seen in each high-power field of the sediment. The cerebrospinal fluid was normal.

Several hours after admission, treatment was started with infusions of physiologic saline solution containing 5 per cent of glucose. On the following morning the red-cell count was 4,700,000, the hemoglobin concentration 13 gm per 100 cc and the urea concentration 53 mg. The urine did not contain measurable amounts of albumin. Infusions were administered over the next few days, without change in the neuropsychiatric picture, and the patient was transferred to the closed ward.

On the 5th day, the treatment was modified to include large doses of nicotinic acid amide, thiamine chloride, ribo-

flavin and brewers' yeast powder.* Within 3 days the disturbances of speech and behavior cleared and the patient became tidy and co-operative. By the 15th day all neurologic signs had returned to normal and the parenteral vitamin and saline therapy was discontinued. The patient's condition continued to improve steadily, his memory returned except for the period of his confusion, and he stated that he felt as though he had had a bad dream. He was discharged on the 23rd day, and remained well for the succeeding 9 months.

In the latter part of August, 1943, the patient became quite stubborn. Periodically thereafter he was confused, ordered his wife and daughter from the house, and on one such occasion attempted to beat them. By October he refused all nourishment except an occasional teaspoonful of milk.

On October 10 the patient suffered a series of convulsive seizures, and on October 12 he was readmitted to the neuropsychiatric ward. Examination at that time revealed severe dehydration. There were pellagrous skin changes on the hands and other exposed parts. The mucous membranes of the mouth and pharynx were reddened, and there was a small ulcer in the pharynx. The conjunctivas were injected. The cardiac status was not different from that of the previous admission. The blood pressure was 215/115. The patient was dysarthric, disoriented as to time and place, restless, inattentive and confused. No significant changes were noted in the eye grounds. The tendon reflexes were normal. The abdominal reflexes could not be elicited, and the plantar responses were flexor Hoffmann's sign was positive in the left hand. Sensory examination demonstrated much the same phenomena as those elicited on the preceding admission. Co-ordination was so poor that the patient was unable to stand even with assistance. Laboratory studies revealed no significant deviations from the normal.

On the day following admission administration of large doses of the crystalline vitamins was started. Within a week all the oral and skin lesions had healed. The patient's emotional reactions improved and he regained the use of his extremities in locomotion. During the hospital stay the blood pressure fluctuated widely but usually remained below 150/90. The patient was discharged 11 days following admission, at which time there were no clinical signs of the neuropsychiatric disturbance. Re-examination over a 4-month period indicated continued minor emotional instability, although the patient was receiving maintenance doses of nicotinic acid amide.

Comment This case illustrates the effect of nutritional inadequacy in a patient with a subclinical encephalopathy of the combined senile-vascular type. The re-establishment of adequate neurologic function and the concurrent disappearance of the somatic signs of deficiency under quasi-controlled therapy indicate that the neuropsychiatric dysfunction was related to the biochemical imbalance. The status of the patient between exacerbations suggests that the clinical picture in the acute phases was largely determined by the underlying aging processes within the brain.

DISCUSSION

The neuropsychiatric manifestations of pellagra usually appear after dermal, oral or gastrointestinal manifestations have developed. In a small proportion of cases, however, neuropsychiatric signs alone are manifest. Elvehjem¹⁴ in reviewing the relation between nicotinic acid and pellagra observed that central nervous tissue retained its ability to oxidize glucose even with severe diminution of the concentration of co-enzyme in the tissue fluids. Such a finding indicates that other factors may play an important role in altering the so-called "resistance of nervous tissue to nicotinic acid deficiency."

*The daily dosages of vitamins were as follows: nicotinic acid amide 0.1 gm intravenously; riboflavin 0.01 gm; thiamine chloride 0.05 gm intravenously; and brewers' yeast powder 15.0 gm.

The major neurohistologic changes in the senile psychoses and in pellagra overlap somewhat in the frontal lobes and in the deeper ganglions. A combination of these two pathologic processes may result in clinical disturbances when either alone is of insufficient magnitude to produce symptoms. Under these conditions a clinical neuropsychiatric disorder may be present with but minimal extraneural signs of pellagra.

The senile person is apt to become mentally disturbed during the course of acute febrile illness, following severe trauma and under emotionally unfavorable conditions. As yet, this liability has not been fully explained. This type of occurrence is evidence of the increased susceptibility of the aging nervous system to adverse environmental changes. Such susceptibility may be attributable to the organic changes within the nervous systems of such patients, just as are the personality changes of the aged.

Personality changes also become manifest in the dietary. Restrictions, both qualitative and quantitative, are not infrequent among elderly patients. Fadism of this sort tends to eliminate valuable foodstuffs from the diet, and its continuation may lead to clinical deficiency states. In this way a cycle is formed in which a fad leads to an inadequate food intake, and the inadequacy to a further loss of appetite and a severer dietary restriction.

The diagnosis of pellagrous encephalopathy in the aged person with psychosis must depend on clinical or laboratory evidence of nicotinic acid deficiency. The neuropsychiatric syndromes produced are not characteristic of pellagra but of the location of the lesions in the central nervous system, and they may occur in a variety of disorders. The response to controlled therapy may be of value in this regard, in which case the diagnosis may be made in retrospect. In general, mucosal and dermal lesions of nicotinic acid or riboflavin deficiency should be sought whenever an aged psychotic patient is examined. Evidence of other nutritional disorders should lead one to investigate further.

Treatment should be largely prophylactic. Persons in the late decades of life should have diets of optimal rather than minimal adequacy. When the maintenance of an adequate diet becomes infeasible, dietary supplements should be administered. For this purpose, either the crystalline vitamins or concentrated extracts may be used. Crystalline preparations may be given parenterally to patients whose intestinal absorption is defective. When deficiency already exists, effective treatment should combine

the above modes of administration. Adequate returns may be expected from adequate nutrition, even in the aged.

SUMMARY

Senile psychosis may be simulated by pellagrous encephalopathy in the aged. The underlying neurologic alterations in the elderly patient may predispose to this occurrence.

The senile-pellagrous type of encephalopathy may respond well to treatment with crystalline vitamin B products or with natural vitamin B concentrates. The recognition of this group of cases may permit effective therapy.

The maintenance of an optimal dietary by the normal aged person as well as by the senile invalid should be a matter of primary importance.

ACUTE INFECTIOUS LYMPHOCYTOSIS IN YOUNG ADULTS

CAPTAIN PETER A DUNCAN, M C , A U S

ACUTE infectious lymphocytosis, a clinical entity featured by a benign relative and absolute increase in the number of small mature lymphocytes, was first described in 1941 by Smith.¹ He presented 2 cases of this disease and expressed the opinion that the group of patients reported by Reversbach and Lenert² and 1 case described by Wilson and Cunningham³ belonged in this classification rather than among the cases of infectious mononucleosis, as reported. There were no significant clinical signs or symptoms in any of these cases. Another case of acute infectious lymphocytosis presenting a marked symptomatology has been described,⁴ and the belief was expressed that 2 of the cases reported by Thelander and Shaw⁵ as infectious mononucleosis should be classified as acute infectious lymphocytosis. Smith⁶ has recently summarized his experience with acute infectious lymphocytosis and has described 4 additional cases.

To date, all reported cases of acute infectious lymphocytosis have occurred in children under the age of nine. It seemed of interest, therefore, to present 2 cases in young adults.

CASE 1. A 20-year-old soldier was admitted to the station hospital on August 25, 1943. Rubella and epidemic parotitis had occurred in childhood. Otherwise, the past history was not significant. The family history was noncontributory.

For 1 week prior to admission, the patient had a "cold," accompanied by intermittent pains in the back and chest. Additional complaints of stomach cramps, headache and a mild, nonproductive cough eventually developed, fever was demonstrable and the patient was hospitalized.

The temperature on admission was 102°F. Physical examination revealed a slender, well developed young adult appearing neither acutely nor chronically ill. The throat was mildly inflamed, and there was a small collection of mucus in the posterior pharynx. A small, tender lymph node was palpable in the right submaxillary region. The remainder of the examination was normal.

The symptoms completely disappeared within a few hours after admission, but during the first 2 weeks of hospitalization the temperature was elevated each morning to from 99 to 101°F, dropping to normal each afternoon or early evening. On August 30 there appeared a generalized morbilliform rash, which gradually faded and disappeared 4 days after onset. With its disappearance, a few small, nontender, axillary and inguinal lymph nodes became palpable. One week later, these were no longer felt. On September 13, the afternoon temperature was 100.2°F, rising to 104°F the following day. There was then a rapid fall in the temperature, but the patient continued to run a low-grade fever every morning until discharged on September 27.

Agglutination reactions for *Eberthella typhosa*, *Salmonella paratyphi*, *Salmonella schottmülleri* and *Brucella abortus* and the Weil-Felix reaction were negative. A roentgenogram of the chest showed no abnormalities. Repeated examination of the urine gave results within normal limits. The Kahn reaction was negative. The electrocardiograph recorded normal tracings. Heterophil agglutination tests on September 5 and 13 gave negative reactions.

There was a moderate relative and absolute increase in the number of lymphocytes of approximately 2 weeks' duration (Table 1). Its onset occurred during the 1st week, the white-cell count, which had been normal on admission, increasing to 27,850 by the 7th day. Frequent examination of stained smears failed to reveal abnormal or atypical lympho-

cytes. Small mature lymphocytes accounted for the lymphocytosis. The proportion of large mononuclear cells never exceeded 5 per cent. Repeated determinations of the erythrocyte

TABLE 1 White-Cell and Lymphocyte Counts in Case 1

DATE	WHITE CELL COUNT	LYMPHOCYTES			
		SMALL %	LARGE %	TOTAL %	LYMPHOCYTE COUNT
8/26	6 400				
9/2	28 000	83	1	84	24 000
9/3	20 000	77	3	82	16 000
9/4	14 000	76	5	76	11 000
9/5	18 000	60	3	63	12 000
9/6	19 000	77	4	81	15 000
9/8	13 050	77	2	77	10 000
9/11	10 000	57	2	59	5 700
9/15	12 000	46	2	48	5 800
9/21	8 700	37	4	41	3 600

and total polymorphonuclear-cell counts and hemoglobin content were within normal limits. Platelets were always present in the smear in adequate numbers.

CASE 2. A 19-year-old soldier was hospitalized on January 25, 1944. The family and past histories were noncontributory. The patient recalled epidemic parotitis, pertussis and varicella during childhood.

During the day preceding admission, the patient had noted a slight fever, a mild nonproductive cough, frontal headache and nasal obstruction. He was well developed and well nourished. A slight hyperemia of the conjunctivas, nasal mucosa and pharynx was the only abnormal finding observed on physical examination. The temperature on admission was 99.4°F, but thereafter was normal. The patient became asymptomatic 24 hours following hospitalization. Signs of the mild upper respiratory infection persisted for 4 days. Lymph nodes of significant size were never palpable.

A culture of the throat yielded *Staphylococcus albus* and a few pneumococci. A roentgenogram of the chest revealed no abnormalities. Urinalysis gave results within normal limits. The Kahn reaction was negative. Examination of the spinal fluid on January 28 was negative except for a cell count of 40, 40 per cent of which were lymphocytes and 60 per cent polymorphonuclear leukocytes. Re-examination of the spinal fluid on February 5 showed that the cells had dropped to 2 polymorphonuclear leukocytes per cubic millimeter. Heterophil agglutination tests on January 28 and February 5 and 15 gave negative reactions.

A moderate lymphocytosis caused by small mature lymphocytes was likewise present in this patient (Table 2), it was

TABLE 2 White-Cell and Lymphocyte Counts in Case 2

DATE	WHITE CELL COUNT	LYMPHOCYTES			
		SMALL %	LARGE %	TOTAL %	LYMPHOCYTE COUNT
1/25	22 000	65	2	67	15 000
1/26	15 000	63	3	66	10 000
1/27	20 000	65	3	70	14 000
1/28	22 000	55	3	60	13 000
1/29	16 000	64	2	66	11 000
1/30	12 000	62	3	65	7 800
1/31	13 000	68	3	73	9 500
2/1	14 000	57	3	62	8 700
2/2	15 000	58	3	63	9 500
2/3	9 500	38	6	44	4 100
2/4	11 000	40	5	45	5 000
2/5	8 700	37	4	41	3 400
2/6	14 000	31	5	36	5 000
2/9	8 800	31	4	35	3 100
2/15	9 000	25	5	30	2 700
2/19	7 500	23	6	29	2 200

observed over a period of 2 weeks. The maximum white-cell count was 22,000. No immature or atypical lymphocytes were seen at any time. The proportion of large mononuclear cells did not exceed 6 per cent. The platelet count varied

from 225,000 to 315,000. Repeated determinations of the hemoglobin content and the number of red cells were normal. The total number of polymorphonuclear leukocytes was constantly within the normal range. The bleeding and clotting times of the blood were normal.

DISCUSSION

The evidence for the establishment of acute infectious lymphocytosis as a specific entity has recently been summarized by Smith.⁶ He differentiates it from infectious mononucleosis, acute lymphatic leukemia and other infections associated with a lymphocytosis in children. The reader is referred to his paper for a comprehensive discussion.

I have encountered one other, apparently rare, consideration in the differential diagnosis of an absolute lymphocytosis in children. A relative and absolute increase in the number of small mature lymphocytes was observed during the administration of sulfadiazine to a child with a purulent otitis media in whom the initial reaction of the blood was that of a polynucleosis. The extent of the lymphocytosis was similar to that experienced in acute infectious lymphocytosis in children, but the white-cell count promptly returned to normal following discontinuance of the drug.

Study of the present 2 cases of acute infectious lymphocytosis in adults indicates that the disease is closely similar to that observed in children. Both patients had clinical evidence of a mild upper-respiratory infection. In addition, Case 1 presented symptoms usually attributed to a mild infection of the influenzal type. Both had clinical courses similar to that noted in several of the children previously reported (Cases R S and E S⁶). The patient in Case 1 had a morbilliform rash lasting for four days during the first week of the disease. A rash of this type has not been previously encountered in acute infectious lymphocytosis. It was similar to the rash reported in 57 to 18.5 per cent of cases of infectious mononucleosis. An extremely irregular febrile reaction was observed in Case 1 throughout most of the period of hospitalization. Similar temperature curves were observed in 2 of the children with acute infectious lymphocytosis (Case E N⁴ and Case M S⁶).

As stated above, the spinal fluid early in the course of the disease in Case 2 contained 40 cells per cubic millimeter, only 40 per cent of which were lymphocytes. This finding was similar to that encountered in 2 children reported by Thelander and Shaw.⁵ Although these patients presented symptoms of meningitis and encephalitis, respectively, there were no signs or symptoms, except for headache, referable to the nervous system in Case 2. The spinal fluid has been examined in only 1 other case of this disease (Case M S⁶) and was found to be normal. One other child with acute infectious lymphocytosis presented symptoms compatible with neurologic involvement, but examination of the spinal fluid was not done.⁴ Smith⁹ has recently

encountered 2 children with acute infectious lymphocytosis in whom the clinical picture resembled that of poliomyelitis. Collectively, these cases indicate neurologic involvement in an appreciable percentage of reported cases of acute infectious lymphocytosis, and suggest that this disease be included in the differential diagnosis of patients presenting neurologic signs and symptoms in association with an acute febrile illness.

The duration of the absolute lymphocytosis in adults appears to be shorter than that observed in children. The latter usually have elevated lymphocyte counts for periods of three to five weeks, in contrast to the shorter intervals observed in the present adult cases. Likewise, the maximum leukocyte counts of 27,850 and 22,000 encountered in the present cases were well below the usual range of 40,000 to 110,000 in children. A leukocytosis of 18,600 encountered in an eight-year-old girl has been the only exception to this range in children (Case E S⁶). All other aspects of the hematologic picture in the present cases were similar to those previously described.

Infectious mononucleosis presents the greatest problem in the differential diagnosis of acute infectious lymphocytosis in adults. Although still to be considered, the other diseases discussed in the differential diagnosis of acute infectious lymphocytosis by Smith⁶ are not so frequently encountered in adults. From August 1, 1943, to August 1, 1944, 12 cases of a relative and absolute lymphocytosis were observed in this station hospital. The cases of acute infectious lymphocytosis were the only ones encountered up to February 5, 1944. Ten cases of infectious mononucleosis were observed during the following five-month period. Although histories were obtained of contact between several of the patients with infectious mononucleosis, there was no possible contact between the patients with the two diseases. In spite of certain similarities, careful clinical, hematologic and serologic study of these cases corroborated the factors of differentiation between infectious mononucleosis and acute infectious lymphocytosis stressed by Smith.⁶

Clinically, the patients with infectious mononucleosis were sicker and for a longer period than those described in detail in this paper. The symptomatology of the cases of infectious mononucleosis conformed to that described in recent reviews.^{7, 10} In most of the reported cases of acute infectious lymphocytosis, the clinical findings have been minimal or completely absent. It must be remembered, however, that there have been cases (Case E N⁴ and Case M S⁶) in which the clinical picture was that of an acute and severe illness. The 10 cases of infectious mononucleosis had a marked lymphadenopathy, which sharply demarcated them from the minimal amount or complete absence of lymph-node enlargement encountered in the 2 cases of acute infectious lymphocytosis.

The principal point in the differential diagnosis of these diseases was made by frequent examinations of the peripheral blood smear throughout the course of the maximum white-cell counts in both diseases were within the same range. Thus, the extent of the white-cell count in adults cannot be used as a point of difference between the two diseases as it is in children, in whom the leukocytosis in acute infectious lymphocytosis is much higher than it is in infectious mononucleosis. Although there was considerable variation in the number of large atypical mononuclear cells in the differential smear from day to day in the cases of infectious mononucleosis, they were always present in significant proportions (8 per cent or more). Repeated examinations of the peripheral blood smear in the cases of acute infectious lymphocytosis failed to reveal the presence of these large atypical mononuclear cells at any time. The lymphocytosis was due in its entirety to small, mature lymphocytes. Although not sharply differentiated, the period of absolute lymphocytosis in the cases of infectious mononucleosis tended to be shorter—five to twelve days—than that encountered in the cases of acute infectious lymphocytosis, although it is well known that in the former the lymphocytosis may continue for months. Most of the cases of infectious mononucleosis showed a rather persistent relative lymphocytosis, with the continued presence of large atypical mononuclear cells, whereas the cases of acute infectious lymphocytosis returned promptly to a normal differential once the period of the absolute lymphocytosis had been completed.

The heterophil agglutination reaction has been uniformly negative in all cases of acute infectious lymphocytosis. In a recently reported series of 143 cases of infectious mononucleosis, the reaction was positive in significant titers (1:64 or higher) in 83 per cent.⁷ Nine of the 10 patients with infectious mononucleosis in the present study had titers of 1:64 or higher. The remaining patient, who presented typical hematologic findings, had a maximum titer of 1:28. Therefore the heterophil

agglutination reaction appears to be a negative laboratory test of considerable importance in the differential diagnosis of acute infectious lymphocytosis.

A review of the present literature on acute infectious lymphocytosis suggests that this disease is infrequently encountered. It is obvious that, with the minimal and varied clinical findings of many of the reported cases, the diagnosis of this disease will be missed unless a hematologic study is routinely accomplished. On the other hand, a more widespread familiarity with the varied manifestations of acute infectious lymphocytosis will result in its detection in a frequency greater than the reported cases indicate.

SUMMARY

Two cases of acute infectious lymphocytosis occurring in young adults are reported. The hematologic findings were similar to those previously recorded in children except that the extent of the lymphocytosis was less and its duration was shorter. A morbilliform rash was present for four days in Case 1, a finding not previously described in this disease. Changes in the spinal fluid were observed in Case 2, without clinical evidence of involvement of the nervous system.

The clinical, hematologic and serologic findings in these cases are compared with those in 10 cases of infectious mononucleosis.

CLINICAL NOTE

PEDICULOSIS CORPORIS AND LEG
ULCERS*

GEORGE E MORRIS, M D †

BOSTON

WHEN a middle-aged patient confronts a physician with ulcers of the legs for diagnosis and treatment, immediately such causes as venous

FIGURE 1

stasis, late spirochetal infection, cancer, erythema induratum, tuberculosis, sickle-cell disease, ecthyma, trauma, diabetes and self-infliction are considered. The dermatologist if consulted thinks also of deep mycologic infection, — blastomycosis, sporotrichosis, actinomycosis and so forth, — phagedenic ulcers, microaerophilic hemolytic strepto-

coccus infections, drug (especially halogen) ingestion, leprosy, mycosis fungoides, necrobiosis lipodica diabeticorum, scleroderma, leishmaniasis, cutaneous diphtheria, flea bites and tropical ulcers. To this list should be added the bites of the body louse, with the resultant scratching, infection and ulceration. In a large hospital clinic, ulcers of the legs due to pediculosis corporis rank second in frequency only to the so-called "stasis" (varicose) ulcers.

Several excellent textbooks on dermatology¹⁻⁴ fail to mention such ulcerations in the discussion of either pediculosis or ulcers. Other textbooks^{5,6} mention that ulcerations may occur but fail to stress adequately their occurrence on the legs. Thus, it is good practice to examine the entire body and clothing of patients with unexplained ulcers of the legs.

The ulcers are usually bilateral and multiple, and are most numerous on the lower third of the leg (Fig 1). They are shallow, oval or rounded (but may occasionally have straight sides), and generally ooze a syrupy fluid. They are ordinarily surrounded by an area of erythema. The legs frequently show localized hemorrhagic scratch marks, but the typical parallel linear scratch marks of pediculosis corporis are not usually present.

Such lesions respond well to eradication of the body lice, followed by the local application on alternate days of a 1 per cent aqueous solution of gentian violet and 2 per cent allantoin in a water-soluble emulsion base.

SUMMARY

Multiple ulcers of the legs are frequently due to infestation of the clothing with body lice. Search for such parasites should be made in all suspicious cases.

MEDICAL PROGRESS

MYCOTIC INFECTIONS (Concluded)*

JOHN GODWIN DOWNING, M D,† AND NORMAN F CONANT, PH D ‡

BOSTON, MASSACHUSETTS, AND DURHAM, NORTH CAROLINA

SYSTEMIC MYCOSES

Included in this category are diseases caused by a wide variety of fungi, each of which may invade any tissue of the body, producing widespread infection resulting in death. These fungi induce a granulomatous type of infection, and differential diagnosis must include tuberculosis, syphilis, granulomas and neoplasms

Coccidioidomycosis

This is a highly infectious disease caused by *Coccidioides immitis* that produces a high incidence of infection, as shown by positive skin tests with coccidioidin, among native populations in the endemic areas of the San Joaquin Valley in California, around Phoenix and Tucson in Arizona and around San Angelo in central western Texas. Scattered cases have been reported from other areas in the United States, but most of them can be traced back to the localities mentioned above. A few cases have been reported from outside the United States, namely, South America, the Hawaiian Islands and Italy.

The fungus appears in the sputum, exudates and tissues as a large, single-celled, thick-walled spherule that reproduces by endosporulation. In culture, the fungus grows as a filamentous mold and reproduces by means of arthrospores, spores produced by fragmentation of its filaments.

Coccidioidomycosis is recognized as a pulmonary infection contracted by inhalation of the arthrospores of the fungus in dust, it simulates tuberculosis in all its clinical manifestations. The disease is divided into an acute primary infection of the lungs, usually followed by complete recovery, and a chronic progressive secondary granulomatous infection with a mortality rate of approximately 50 per cent.

The acute primary infection, with an incubation period of eight to fourteen days, simulates a cold, "flu" or bronchopneumonia. The symptoms may be mild or range in severity to severe prostration with chills, fever, malaise, anorexia, night sweats, headache, backache, pleurisy and rapid loss of weight. Physical signs in the chest are usually absent, and the x-ray films may be clear or may be indistinguishable from those of primary tuber-

culosis. Such an x-ray picture of the lungs clears rapidly, however. In about 2 to 5 per cent of such infections an associated hypersensitivity develops in five to fourteen days, manifested by erythema nodosum or erythema multiforme. Such skin lesions vary in duration from one to eight weeks, but the pigmentation may remain for months. Diagnosis is established by finding the large, nonbudding, endospore-filled spherules in the sputum, by culture and animal inoculation and by a skin test with 0.1 cc of a 1:1000 dilution of coccidioidin. Complement fixation and precipitin tests, using coccidioidin as the antigen, are useful diagnostic acids.

The chronic secondary progressive granulomatous infection is the result of an endogenous dissemination of the fungus either during the initial infection or later. Any organ of the body may be infected, and the symptoms are indistinguishable from those of tuberculosis. Demonstrating the organism is the only satisfactory means of establishing the diagnosis. Serologic (complement fixation and precipitation) tests are usually positive, but owing to the severity of the disease the patient may be anergic and give a negative skin test even with a 1:10 dilution of coccidioidin.

Treatment of the primary infection is symptomatic. Salicylates are helpful, but there is no specific treatment. Bed rest until the sedimentation rate and white-cell count are normal and until the lung findings, if any, show progressive clearing is all that can be accomplished. Recovery without sequelae should be expected.

Treatment of the secondary progressive infection is not satisfactory, and the mortality rate approaches 50 per cent. Many drugs have been used, but no consistent method of treatment has been established. Bed rest with a high-vitamin, high-calorie diet, as with tuberculosis, is advocated to support any resistance to the infection that the patient may have.

From 1894 to 1896, when Rixford⁸⁰ and Rixford and Gilchrist⁸¹ first described this infection in the United States, until 1936, the disease was known as coccidioidal granuloma and thought to be highly fatal. Gifford⁸² and Dickson,⁸³⁻⁸⁶ however, established the fact that a disease known locally in the San Joaquin Valley as "valley fever," "San Joaquin Valley fever," "desert fever" or "desert rheumatism" was a benign nonfatal form of coccidioidal granuloma not previously recognized.

Epidemiologic studies of this disease have shown that the fungus occurs in the soil,⁸⁷⁻⁸⁹ in wild ro-

dents,^{90, 91} cattle and sheep⁹²⁻⁹⁷ and in dogs that have lived in endemic areas⁹⁸ The disease is acquired by inhalation of windblown dust laden with the spores of the saprophytic cultural form of *C. immitis* and not by a person to person or an animal to person transfer of the spherules found in the human or animal tissues during the disease⁹⁹

North American Blastomycosis

North American blastomycosis or Gilchrist's disease is a chronic infection caused by *Blastomyces dermatitidis*, with characteristic skin lesions and systemic involvement, particularly of the lungs, that is indistinguishable clinically from tuberculosis. The disease seems to be confined to the United States and Canada, since no adequately proved cases have been reported elsewhere.

B. dermatitidis appears in the sputum, exudates and tissues as a large, round, thick-walled, single budding organism. Cultured at incubator temperature, the fungus remains in the budding yeastlike parasitic form. Cultured at room temperature, however, the fungus develops a filamentous growth that reproduces by conidial formation from the sides of the filaments or from the ends of short branches.

In cutaneous blastomycosis the lesions occur on the exposed parts of the body, — face, neck, dorsum of hands, wrists and forearms, ankles and forelegs, — where they resemble the lesions of verrucous tuberculosis cutis or epitheliomas. Beginning as a papulopustule, such lesions slowly spread peripherally, break down to reveal a red granulating base covered with a dirty pink exudate and a raised papilliform or verrucous border with miliary-like abscesses. Occasional lesions seen in the genitoretal region should not be mistaken for granuloma inguinale. The clinical diagnosis is confirmed by demonstrating the large, round, thick-walled, single budding fungus in the exudate, crusts or pus from the peripheral miliary abscesses.

Systemic blastomycosis closely mimics tuberculosis. The fungus enters the body by way of the respiratory tract, and the lungs, skin and bones are the most frequently involved organs. Multiple subcutaneous gummalike nodules may appear anywhere on the body, and rupture to free a bloody pus. With widespread blood-stream dissemination of the fungus, the liver, spleen, kidneys and central nervous system are the usual sites of infection. The spleen and liver lesions are minimal, and the intestine is not invaded. Until skin involvement by subcutaneous abscess formation occurs, tuberculosis is the usual diagnosis. All attempts should be made, however, to find the fungus in the sputum or exudates when repeated examinations for the acid-fast tubercle bacillus are negative.

Treatment should not be started on any case of blastomycosis until an intracutaneous skin test with 0.1 cc. of heat-killed vaccine of the fungus has been done to determine the sensitivity of the patient to

the fungus or its products. Martin and Smith¹¹ have shown that lesions of patients sensitive to such materials rapidly spread when iodides or x-rays, or both, are used. Patients found not to be sensitive may be started immediately on potassium iodide by mouth or sodium iodide intravenously, whereas those patients who are sensitive should be given a course of desensitization before iodides are administered. Good results in the treatment of cutaneous blastomycosis should be expected. Results of the treatment of systemic blastomycosis depend on an early diagnosis and the immunologic status of the patient, as outlined by Conant et al.¹⁰¹

Since blastomycosis was described by Gilchrist¹² in 1896 and the fungus named *B. dermatitidis* by Gilchrist and Stokes¹⁰³ in 1898, several different fungi have been isolated from the disease and described as new genera or species. Comparative studies of these different fungi by Benham¹⁰⁴ and Conant¹⁰⁵ have shown them to be identical and the disease to be caused by a single etiologic agent.

The source of infection with *B. dermatitidis* has not been proved. Stober¹⁰⁶ isolated a white mold from the dwelling of a patient, but the fungus was not sufficiently described to prove it to be *B. dermatitidis*. Because of this report, it was thought that poor, unhygienic living conditions allowed contact with the fungus, which could be found in such places. There is evidence, also, that the fungus occurs in nature and that cutaneous blastomycosis is contracted by an introduction of the organism into the skin through abrasions or trauma. Toepel¹⁰⁷ reported a case following a thorn prick, and McKenty and Morgan¹⁰⁸ one from a scratch on the face. Robinson¹⁰⁹ described a patient whose onset followed a barefoot walk.

Ravogli,¹¹⁰ Werley¹¹¹ and Wohl¹¹² suggested the possibility that the disease was contracted from handling animals or their products, but failed to show the fungus in such materials. That animals do have the disease has been shown by Martin and Smith¹¹³ and Foshay and Madden¹¹⁴ in their reports of spontaneous infections in dogs. There has been, however, no proved transmission of the fungus from animal to man. The single transmission from man to man was reported by Evans¹¹⁵ in a physician who, at necropsy of a case of blastomycosis, cut his finger.

There seems to be no endemic area of the disease. Sporadic cases occur throughout the United States, and the lack or number of cases is an index only of the interest shown in the disease.

South American Blastomycosis

South American blastomycosis, paracoccidioides granuloma or Lutz-Splendore's disease is a chronic granulomatous disease of the mucous membranes of the mouth and regional lymph nodes, skin of the face and internal organs caused by *Paracoccidioides brasiliensis* or *P. cerebriformis*. The disease is largely confined to Brazil, but is reported occasionally from

her countries in South America, namely, Argentina, Paraguay, Peru and Venezuela

P. brasiliensis and *P. cerebriformis* appear in the exudates or scrapings from the lesions as large, round, multiple budding, thick-walled organisms. The buds, arranged around the periphery of the parent cells, may be as small as cocci (1 to 2 microns) or 30 microns in diameter. Cultured at incubator temperature these fungi develop yeastlike colonies not unlike those of *Blastomyces dermatitidis*. The multiple budding, parasitic tissue forms are found in such cultures. When cultured at room temperature, *P. brasiliensis* develops a filamentous colony that is cottony and *P. cerebriformis* develops a filamentous colony that is waxy, being smooth or wrinkled.

This disease has been divided into three distinct types — the mucocutaneous, the lymphangitic and the visceral. In the mucocutaneous type of infection, the portal of entry is the mouth, with ulcerating, vegetative, papillomatous lesions occurring on the buccal mucosa and spreading to the skin of the face around the mouth and nose. The regional lymphatics are invaded, and lymphatic invasion to the axillary, inguinal and other nodes of the body is not infrequent. Individual lesions around the mouth and nose are similar to those of mucocutaneous leishmaniasis and yaws, and a differential diagnosis can be obtained only by a laboratory study of material obtained from the lesions.

The lymphangitic type of infection is characterized by massive infection of the lymph nodes of the neck, with no external lesions until necrosis and drainage take place. The portal of entry is probably the mouth, with direct infection of the lymphoid tissue without mucosal lesions.

Visceral infection takes place through the intestinal tract, as evidenced by numerous lesions in the lymphoid tissues of the intestine. Massive infection of the lymph nodes throughout the viscera, enlargement of the spleen and liver and other organs and dissemination of the fungus throughout the body produce a highly fatal form of the disease.

Clinically, this disease differs from North American blastomycosis in that the portal of entry is the mouth, that the intestines are often infected and that in only 15 to 20 per cent of the cases are the lungs involved, in Gilchrist's disease the portal of entry is the respiratory tract or skin, the intestines are not infected and, in the systemic cases, 95 per cent have lung lesions.

Early reports from South America have stated that this disease is invariably fatal. Iodides have occasionally been employed with some success, but their use usually causes the lesions to spread. In view of the effect of iodides in hypersensitive cases of North American blastomycosis, the use of a desensitizing vaccine before iodide treatment in the South American disease seems indicated. Recent reports have shown that the sulfonamides give almost im-

mediate relief, with slow healing of the lesions. These drugs must be given in daily doses over long periods of time — in some cases as long as one to two years.

South American blastomycosis was described first in its cutaneous form by Lutz¹¹⁶ and Carini¹¹⁷ in 1908. The first generalized infection was recognized by Splendore,¹¹⁸ who¹¹⁹ later named the fungus *Zymonema brasiliense*. For a period of years this fungus was thought to be identical with *Coccidioides immitis*.¹²⁰⁻¹²³ In 1930, however, Almeida¹²⁴ showed by comparative studies of material obtained from cases of coccidioidomycosis occurring in the United States and material obtained from Brazilian cases that the two diseases were different. He named the South American fungus *P. brasiliensis*. The cases of coccidioidomycosis reported from South America, therefore, were cases of blastomycosis caused by the multiple-budding *Paracoccidioides* that had been mistaken for the nonbudding, endospore-forming coccidioides. Only three cases of coccidioidomycosis have occurred in South America. Posadas¹²⁵ described the disease from Buenos Aires in 1892 but failed to name the fungus. Fonseca¹²¹ reported a case from the Chaco of Argentina in 1928 but named the fungus *Pseudococcidioides mazzai*, and Negroni and Villafane Lastra¹²⁶ reported a case from Serrezeuela, Province of Cordoba, also in Argentina, in 1939, but named the fungus *Trichosporon proteolyticum*.

The South American disease is said to be caused by three distinct species of *Paracoccidioides* — *P. brasiliensis* (Almeida¹²⁴), *P. cerebriformis* (Moore¹²⁷) and *P. tenuis* (Moore¹²⁸). Several investigators,¹²⁹⁻¹³¹ however, would reduce these species to synonymy, and Conant and Howell¹³² would place them all in the genus *Blastomyces* as a single species, *B. brasiliensis*.

Cryptococcosis

Cryptococcosis (European blastomycosis, Busse-Buschke's disease, torulosis or *Torula meningitis*) is a subacute or chronic granulomatous infection of man and animals caused by *Cryptococcus neoformans*. This disease may be divided into cutaneous and systemic forms of infection, with the latter always terminating in meningitis because of the marked predilection of the fungus for nervous tissue.

C. neoformans appears in tissue, exudates, sputum and spinal fluid as a large, round, thick-walled budding organism surrounded by a thick capsule. In culture, at any temperature, the fungus remains yeastlike, mucoid, glistening and tan to dark brown. The same type of budding cells with wide capsules are found in cultures as in material from lesions.

Cutaneous cryptococcosis is characterized by acneform pustules that may ulcerate, granuloma-like ulcers, subcutaneous tumors or deep-seated abscesses that may develop anywhere on the body — cheek, neck, abdomen, thigh and groin. Such lesions are usually followed by cerebrospinal involvement or a generalized infection.

Infection of the central nervous system is characterized by protean clinical symptoms — headache, dizziness or faintness, convulsions, nausea and vomiting and signs of increased meningeal irritation with stiffness of the neck and positive Kernig and Brudzinski signs. The spinal-fluid pressure is increased, the cell count is high, and the globulin and albumin are increased, but the sugar content is low. A differential diagnosis would include tuberculous meningitis, syphilis, encephalitis, brain abscess, brain tumor and central-nervous-system degeneration.

Lung infections resemble tuberculosis or a neoplasm by x-ray examination, and diagnosis can be made only by finding the fungus in the sputum by direct examination or by culture.

India-ink preparations of gummy, blood-stained exudates from subcutaneous tumors, abscesses or ulcerations and sputum and wet Giemsa stains of frozen sections provide the best means of demonstrating *C. neoformans* in such materials. The spinal fluid should be centrifuged, and the sediment examined by the India-ink method. Such examinations reveal the round, thick-walled budding fungus surrounded by its characteristic and diagnostic wide gelatinous capsule.

Treatment of cutaneous cryptococcosis has not been too successful, and the disease usually terminates fatally with meningitis. Kessel and Holtzworth¹³³ reported a successful cure by oral iodides and x-ray treatment to individual lesions on the right and left breasts and amputation of a leg with a knee lesion that failed to heal. Dienst¹³⁴ reported a cure after oral iodides and x-ray treatment of a subcutaneous tumor attached to the tenth rib on the right side.

Central-nervous-system cryptococcosis has had a high mortality, not only because the diagnosis has not always been readily apparent, but also because there seemed to be no specific drug. Recent reports, however, have shown that the sulfonamides may be effective. Reeves, Butt and Hammack¹³⁵ reported recovery after treatment with sulfapyridine, and Marshall and Teed¹³⁶ reported recovery of a patient after treatment with sulfadiazine. Conant et al.¹³⁷ have reported a cure of a lung infection after sulfadiazine administration. These reports are a contradiction to the in-vitro studies of Keeney et al.¹³⁸ in which sodium sulfathiazole, sodium sulfadiazine and sodium sulfamerazine showed no effect on the growth of *C. neoformans* in culture. What part penicillin will eventually play in the treatment of this disease can be determined only after clinical trial. Keeney et al.¹³⁹ report no effect on the fungus in vitro, but Dawson et al.¹⁴⁰ report a killing effect comparable to that of *Staphylococcus aureus*. Jones and Klinck,¹⁴¹ however, have reported a case in which both sodium sulfadiazine and penicillin were of no value. Also, in-vitro experiments with cultures and in-vivo experiments with mice showed both these drugs to have no effect.

That cryptococcosis as it occurs in this country is the same as Busse-Buschke's disease¹⁴² (European blastomycosis) cannot be doubted, since Benham¹⁴⁴ showed the identity of the etiologic agents. The disease is world-wide in distribution, and the fungus is the same regardless of the type of case from which it is isolated.

C. neoformans was first isolated under natural conditions from peaches by Sanfelice.¹⁴⁵ It has been isolated from animals. Sanfelice¹⁴⁶⁻¹⁴⁷ obtained *S. lithogenes* from an ox and *S. granulomatogenes* from swine, Frothingham¹⁴⁸ *Torula* sp. from a horse, Harrison¹⁴⁹ *T. nasalis* from a horse, and Weidman and Ratcliffe¹⁵⁰ *T. histolytica* from a cheetah. Although the fungus has been isolated from nature and animals, there have been no reports of a natural infection or of transmission from animal to man. The portal of entry in man is thought to be the skin, respiratory tract or intestinal tract. Weis,¹⁵¹ who compared *C. neoformans* with a species of *Blastomyces* (*T. klein*) isolated from milk by Klein,¹⁵² suggests that the intestine can, at times, be the portal of entry.

Histoplasmosis

Histoplasmosis (Darling's disease or reticuloendothelial cytomycosis) is an infection of the endothelial cells of the reticuloendothelial system by *Histoplasma capsulatum*. Because of the intracellular distribution of the fungus throughout the body by such a system, the organism resembles *Leishmania donovani* and the disease resembles kala-azar.

H. capsulatum appears in the mononuclear or polymorphonuclear cells of peripheral blood smears, sternal bone-marrow smears, splenic-pulp smears and in tissue sections as a small, oval, sometimes budding cell 1 to 5 microns in diameter. Cultures of such materials on blood agar at incubator temperature develop the small, budding, yeastlike cells. Cultures grown at room temperature, however, develop a filamentous moldlike colony, which may be identified by the characteristic large tuberculate chlamydospores produced from the filaments.

Darling's original description of the disease stated that fever, anemia, leukopenia, splenomegaly, hepatomegaly and emaciation were the outstanding symptoms. Such symptoms may also be those of kala-azar. With the increasing number of cases described within the past few years, it has become evident that the symptomatology varies considerably. Marked lymphadenopathy may necessitate a differential diagnosis to include Hodgkin's disease, lymphosarcoma and aplastic anemia. Many patients have shown ulceration of the tongue, pharynx or larynx and ulceration of the mucosa of the nose that might be mistaken for carcinoma. Several types of skin lesions have been described — papular eruptions, deep punched-out ulcers, petechial hemorrhages and bullous lesions. In the lungs, the parenchymal changes and scattered miliary

esions may be typical of tuberculosis. Symptoms referable to the intestinal tract are diarrhea, hemorrhage and vomiting, with frequent ulceration of the lymphoid tissue found at autopsy.

Treatment of this disease has not been successful in spite of the use of a wide variety of drugs.¹⁵³

Histoplasmosis was first described by Darling¹⁵⁴⁻¹⁵⁶ from the Canal Zone and considered to be a tropical disease caused by a protozoan, *H. capsulatum*, closely related to the Leishman-Donovan bodies reported in cases of kala-azar. Rocha-Lima¹⁵⁷ reported the occurrence of budding by these organisms and hence considered them to be a fungus, *Cryptococcus*. Hansmann and Schenken^{158, 159} in 1933 and 1934 and DeMonbreun¹⁶⁰ in 1934 were able to culture the organism and definitely proved that it was a fungus. Since then, numerous cases have been described, showing the disease to have a world-wide temperate and subtropical distribution, with the majority of cases occurring within the United States. Meleney¹⁶¹ reviewed 32 cases up to 1940, and at the present time 74 cases have been reported. The recent excellent review by Parsons and Zarafonetis¹⁵³ discusses 71 of these. In this publication may be found the best discussion of the disease to date.

Actinomycosis

Actinomycosis is a chronic suppurative, purulo-granulomatous type of infection characterized by the formation of multiple draining sinuses and caused by a single anaerobic species of *Actinomyces*, *A. bovis*, and several aerobic species of *Nocardia* (*Actinomyces*).

Such fungi appear in the tissues, sinus walls or pus as macroscopic granules, which may be yellowish-white, red or black. Microscopically, these granules are composed of a tangled mass of delicate (1 micron in diameter) branching filaments, which are sometimes terminated at the periphery of the granule by broad sheaths, giving the appearance of clubs. When stained by Gram's method, the filaments are gram-positive, and the sheaths, gram-negative, in some species the filaments are also acid-fast.

Cervicofacial actinomycosis, caused by *A. bovis*, is probably the most frequent clinical type of the disease. There is usually a previous history of tooth extraction or infection referable to the teeth followed, after varying periods of time, by a direct extension of an infection through the tissues of the lower jaw and neck. Extensive cellular infiltration of the lesion produces a tumor-like hard mass, from which abscesses rupture, leaving multiple draining sinuses. The sanguinopurulent pus draining from such sinuses contains the characteristic granules. Occasional extension of the infection to the cranial cavity results in brain abscesses.

Pulmonary actinomycosis is characterized by the chronicity of the infection, often with minimal symptoms. Cough, low-grade fever, malaise and

loss of weight are the usual findings. X-ray films of the lungs may be typical of tuberculosis with apical lesions or may suggest neoplasm with a hilar mass, but usually the infection is confined to the lower half of the lungs. Involvement of the pleura with effusion, adhesions and thickening is often found in advanced cases. The ribs are frequently invaded. The diagnosis may not become apparent until direct extension of the infection to the thoracic wall produces abscess formation and draining sinuses, from which the granules are recovered.

Metastatic cerebral abscesses or meningitis is a frequent complication of primary lung infection. Actinomycosis of the central nervous system usually does not present symptoms referable to a distinct clinical entity. Spontaneous remissions, however, are more frequent in this disease than in those caused by bacteria.

Abdominal actinomycosis usually originates in the region of the appendix and cecum, presenting the picture of subacute appendicitis. Often the disease follows appendectomy, with failure of the scar to heal completely or a breaking through of a sinus in the old scar or in the region of the navel. Irregular tender abdominal masses may be felt, the viscera usually become infected, as do the vertebral bodies of the spinal column. Until a sinus or sinuses appear in the abdominal wall or groin that drain pus containing the granules, these abdominal lesions present difficult diagnostic problems.

Actinomycotic infections of the limbs (mycetoma) are caused by aerobic species of *Nocardia* (*Actinomyces*). The infected foot, knee, hand or arm becomes swollen and deformed, with abscess formation and draining sinuses appearing throughout the mass. In this type of infection the granules may be colored (red or black) in contrast to the sulfur-colored granule of *A. bovis*. Several species may cause such a disease — *N. asteroides*, *N. brasiliensis*, *N. mexicana*, *N. madurae*, *N. paraguayensis* and *N. pelletieri*. These species are identified by their reactions on milk, gelatin, serum and tyrosinase agar, type of growth on Czapek's agar and Sabouraud's agar, production of pigment, odor and, finally, their microscopic morphology and staining reactions (some are acid-fast). *N. asteroides* has been isolated not only from mycetoma but also from cases of diffuse peritonitis, of pseudotuberculosis with cerebrospinal meningitis and of brain abscess.

Treatment of actinomycosis by adequate surgical drainage combined with x-ray therapy and iodides has proved successful, particularly in cervicofacial infections. With the advent of sulfonamides and penicillin, more specific drugs may now be used with surgical drainage to combat the more difficult thoracic and abdominal cases. The sulfonamides and penicillin may act only against secondary bacterial infections and allow more radical surgery. Cutting and Gebhardt,¹⁶² however, showed sulfathiazole and

sulfadiazine to have some inhibiting effect on the growth of *A. hominis*. Benbow, Smith and Grimson¹⁶³ reported excellent results with sulfadiazine and iodides in pulmonary actinomycosis caused by *N. asteroides*. Keeney et al.¹²⁰ have shown penicillin to be effective against *A. bovis* in culture.

Cultures should be attempted in every case to determine the type of infecting fungus, aerobic or anaerobic. Cultivation of infected materials on common bacteriologic media and Sabouraud's agar is sufficient to isolate the aerobic species. The anaerobic *A. bovis*, however, can be isolated only by more exacting methods. Rosebury, Epps and Clark¹⁶⁴ used brain-heart-infusion agar plates, to allow streaking and subsequent picking of well isolated colonies. Such plates were incubated in anaerobic jars in the presence of 5 per cent carbon dioxide. Although shake agar cultures, chopped-meat medium and dextrose broth may also be used successfully with uncontaminated materials, the above method of culture is superior when contaminants are present.

The source of infection with *A. bovis* is endogenous. Several reports of the cultivation of this fungus from tonsillar crypts and carious teeth have established the human mouth as the habitat of this anaerobic species.¹⁶⁶⁻¹⁷⁴ Gordan and Hagan¹⁷⁵ were able to cultivate aerobic acid-fast *Nocardia* (*Actinomyces*) from soil samples and to show one to be pathogenic for rabbits. The pathogenic aerobic species, therefore, probably occur in the soil and are introduced into the body through the skin (mycetoma) or through the respiratory tract or intestine (systemic).

Moniliasis

Of all the mycotic infections, moniliasis is the most difficult to prove by clinical or laboratory methods. Species of the genus *Candida* (*Monilia*) have been isolated from normal mouths,¹⁷⁶ normal intestinal tracts,¹⁷⁷⁻¹⁷⁸ the vagina¹⁷⁹⁻¹⁸⁰ and the skin.¹⁷⁷ Such fungi can be found in the sputum of recognized pulmonary diseases, such as tuberculosis and carcinoma. They are also found in the stools from diseases in which diarrhea is a symptom, such as sprue¹⁸¹ and pernicious anemia.¹⁸² The prevalence of these fungi in normal conditions and diseases in which other etiologic agents are known to be the cause makes the diagnosis of moniliasis possible only by exclusion.

Species of *Candida* appear in clinical materials as small, oval budding cells with occasional mycelial elements. They are gram-positive when stained by Gram's method. In culture on Sabouraud's medium they develop smooth, white, yeast-like colonies, with oval budding cells on the surface and a mycelium penetrating the agar. Such cultures have a distinct yeasty odor. Only a single species, *Candida* (*Monilia*) *albicans*, is pathogenic.

C. albicans may be the primary cause of disease in a number of clinically recognized conditions. Thrush,

or infection of the mucous membranes of the mouth, is encountered more frequently in children than in adults. On the mucosa of the mouth are found extensive or scattered creamy white patches that reveal, on microscopic examination, the budding cells and mycelial elements of *Candida*.

Perlèche is an infection of the corners of the mouth characterized by macerated, eroded or fissured lesions from which *C. albicans* can be isolated. Such lesions, however, may be associated with a dietary deficiency, and the fungus, which can be found in normal mouths, may be a secondary contaminant.

Vulvovaginitis is a thrushlike infection of the vaginal mucosa and vulva characterized by irritation, pruritus and discharge. The fungus can be found in smears from the vagina and vulva or cultured from swabs used to collect material from the vagina. Pregnancy and diabetes are predisposing factors in the occurrence of this disease.

Infection of the skin by *C. albicans*, except in systemic infections, is usually confined to areas where closely approximating parts cause, with the aid of perspiration, mechanical irritation and maceration of the tissues. Intertrigo of the axillae, inguinal region and inframammary areas is characterized by erythematous, exudative lesions with sharply margined vesicular or papulosquamous borders. Obesity may be a predisposing factor aiding infection in all the mentioned areas, lactation a factor in the inframammary areas, and diabetes a factor in the intergluteal region. Intertriginous lesions are frequent in dishwashers and others who find it necessary to keep their hands immersed in water over long periods of time.

Onychia and paronychia are often caused by *C. albicans*, being characterized by thickened, grooved, sometimes discolored nails with painful paronychial swellings. Microscopic examination of scrapings in potassium hydroxide preparations reveals the budding yeastlike cells.

Bronchomoniliasis is characterized by a persistent cough, mucoid sputum with white flakes composed of cellular debris and yeastlike cells, a few scattered rales at the lung bases and x-ray films showing a slight to moderate peribronchial thickening. A more extensive invasion of the lungs, producing pulmonary moniliasis, is sometimes indistinguishable from tuberculosis. Malaise, fever, night sweats, chest pain, dyspnea, cough and hemoptysis, with signs of pleural thickening and consolidation, are not unusual. The disease may be acute, with rapid onset, or chronic, with frequent remissions and exacerbations.

Systemic infections are rare but do occur following prolonged refractory stomatitis, glossitis or resistant infections of the skin, particularly in the debilitated patient. Rockwood and Greenwood¹⁸³ and Miale¹⁸⁴ have reported 2 fatal cases, with autopsy findings. In Miale's case and another reported by

Smith and Sano,¹⁸⁵ the central nervous system was involved

Mycotic endocarditis caused by species of *Candida* have been reported in drug addicts by Joachim and Polayes¹⁸⁶ and Wikler and his associates.¹⁸⁷ These cases, however, yielded cultures of *C. parakrusei* and *C. guilliermondii*, two species considered to be non-pathogenic

The possible role of the yeastlike fungi in the pathogenesis of the diseases from which they had been isolated could not be determined until standard methods of classification allowed these organisms to be identified. Hundreds of species differing but slightly from each other have been reported in the medical literature, and until recently, attempts to classify them have resulted in confusion. Comparative studies of cultures by Benham,¹⁸⁸ Martin et al.,¹⁸⁹ Martin and Jones¹⁹⁰ and Langeron and Guerra¹⁹¹ have succeeded in reducing the vast number of reported species to a few well described organisms. These methods can be used to identify quickly and easily yeastlike organisms isolated from any infectious process. The reported incidence of a yeastlike fungus, if identified accurately according to these methods, now has meaning, and the previous confusion regarding their ability to cause disease should be lessened.

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

Weekly Clinicopathological Exercises

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor**

BENJAMIN CASTLEMAN, M.D., *Acting Editor*

EDITH E. PARRIS, *Assistant Editor*

CASE 31321

PRESENTATION OF CASE

A thirty-one-year-old man was admitted to the hospital complaining of weakness, nausea and vomiting.

Five days before admission he slipped on the bottom step of a stairway, falling heavily on the left elbow and the left side of the thoracic cage. The patient's left ribs were strapped, and he was later sent to the emergency ward of this hospital, where he spent the night. The following morning he was fairly comfortable and was discharged. At home he did not feel well, complaining of profuse perspiration, of progressive weakness and of pain in the left thoracic cage. On the day before admission, malaise, nausea and intermittent vomiting appeared. On the day of admission the vomiting recurred. He complained of hiccoughs and of pain in the left upper quadrant of the abdomen and in the left shoulder.

The patient was well developed and well nourished, slightly icteric and in acute distress. The skin was cold and somewhat clammy. The heart and lungs were normal. The abdomen was soft, with no spasm or rebound tenderness, but there was tenderness in the left upper quadrant. There was no definite fluid wave or shifting dullness.

The temperature was 98°F, the pulse 100, and the respirations 25. The blood pressure was 110 systolic, 70 diastolic.

The red-cell count was 2,500,000, and the white-cell count 10,000. The icteric index was 15. A flat plate of the abdomen showed that the stomach was full of air. The splenic shadow was much larger than usual, and the lateral wall of the stomach was slightly serrated. There was no fracture of the ribs overlying the spleen. There were no dilated loops of bowel. Some gas was present in the sigmoid.

Soon after admission an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. CARROLL MILLER. Several points in this patient's story are likely to be confusing to the first observers of such a case. The patient stressed a blow to the left side of the chest, and he had pain in that region. Naturally when an examiner sees such a

patient in the Emergency Ward or at home he thinks immediately of broken ribs, and the obvious treatment for such a condition is strapping to immobilize the broken parts. In addition to pain this patient had weakness, nausea and vomiting. Unless a person is relatively susceptible to pain, a blow in the lower chest does not cause these symptoms, and one must therefore think of other conditions to explain them. I should be interested to know if any blood studies were done when the patient first came into the Emergency Ward.

DR. BENJAMIN CASTLEMAN. None are recorded.

DR. MILLER. He apparently came into the Emergency Ward fairly soon after the accident. He felt reasonably comfortable the next morning and went home. Weakness persisted, however, and he complained of profuse perspiration. In the light of what must have been subsequently found we can explain these symptoms. He began to have malaise, nausea and vomiting. Then, as the condition progressed, he had hiccoughs and pain in the left upper quadrant of the abdomen — a slight shift downward from the chest — and in the left shoulder. When there is trauma to this part of the body one thinks first of injury to the spleen, of course, other viscera that may be injured in that region are the splenic flexure of the colon, the stomach and the kidney. We know that it takes a fairly severe blow to cause a rupture of a hollow viscus and also a reasonably severe blow to cause sufficient contusion or rupture of the kidney to produce symptoms in that region. It may, however, take only an extremely slight blow to cause a laceration or rupture of the spleen.

So far as physical signs are concerned, he must have been pale, although it does not say so in the account of the case. He was slightly icteric, cold, somewhat clammy and definitely sick. These signs go only with what might be called mild shock. The pulse was up a bit, and the blood pressure was perhaps slightly lower than that which a man of his age and condition should have. The positive findings on examination consisted mainly of tenderness in the left upper quadrant of the abdomen. There was no fluid wave or shifting dullness. The laboratory tests showed a marked reduction in the number of red cells, and the white cells were slightly elevated. The icteric index was definitely elevated. A flat plate of the abdomen in such a condition is of considerable interest, and I think that we might see the x-ray films at this point. In such films one should first attempt to demonstrate air under the diaphragm, indicating leakage from a hollow viscus, and then signs of fluid, although these are frequently not easily recognized in the ordinary flat film.

DR. MILFORD D. SCHULZ. The diaphragm is not shown on these films. I do not know whether there is air beneath it, but there certainly is no evidence of air in the peritoneal cavity. The stomach is full of air, and there is some serration of its lateral margin. The lower pole of the spleen is large and round.

*On leave of absence.

I cannot trace the splenic shadow upward I cannot see the edge of the liver I might point out that one femoral head is deformed

DR MILLER Apparently an old process?

DR SCHULZ Yes

DR MILLER Would you say that the splenic flexure of the colon is lower than usual?

DR SCHULZ I do not know I cannot see it

DR MILLER Another condition that I did not mention in association with intra-abdominal injuries is rupture of the liver, which is less likely with injury of the left side of the abdomen than it is with injury of the right side *Contrecoup* rupture, however, does occur

My presumptive diagnosis in this case is a delayed rupture of the spleen We have evidence for this both from the clinical findings and from the statistics reported in the literature There was an increase in the size of the splenic shadow Dr Schulz has pointed out the lower border of the spleen, but there seems to be further density medial to the spleen, pushing the stomach a little more to the midline than it ordinarily would be The course of events in this case is quite typical Immediate rupture of the spleen usually follows a fairly severe injury Late rupture may occur within a week and sometimes even later It is said that 50 per cent of the delayed ruptures take place within the first week and that an additional 25 per cent occur within a two-week period after injury

How can one explain a late rupture? Usually it is due to subcapsular contusion followed by breaking up of the splenic pulp, hemorrhage beneath the capsule and gradual stretching, with increasing tension of the capsule until the capsule breaks and releases both the accumulated and fresh blood There may be a rupture of the capsule at the time of the first injury, but because of certain clotting mechanisms, thrombi form in the region of the spleen, which seal off all the viscera locally, thus preventing spread into the rest of the abdomen No shifting dullness or free fluid in the abdomen was found on physical examination The icteric index may have been increased because of the absorption of hemoglobin from the peritoneal cavity or from spleen, which might have had an accumulation of hemolyzed blood within the splenic capsule There apparently was no intrathoracic disease, and no fluid was demonstrated either by physical or by x-ray examination There was no fracture of the ribs overlying the spleen Of course, one must always suspect fracture of the ribs, with puncture of the pleura and an accumulation of intrapleural blood, when there is a complaint of weakness and pain in the left side following an injury

I think that the important point, presuming my diagnosis to be correct, is that it is easy to skip over such a case lightly and to discharge the patient home, permitting him to carry on full activity after a few days We have had several cases within recent years

in which such an injury has been sustained, these patients have to be watched carefully for the development of symptoms It is important to remember that splenic rupture can occur late, and that when it does it may be one of the most acute abdominal emergencies that we see The patient must be operated on immediately, and even in case of doubt, an exploratory laparotomy is warranted

I shall close my discussion by saying that this patient had a traumatized spleen, probably a subcapsular contusion, at the time of injury, which about five days later ruptured into the peritoneal cavity producing nausea and vomiting, in other words, he had a delayed rupture of the spleen

I neglected to ask about a urinalysis at the time of admission

DR CASTLEMAN It was negative

Have you anything further to say about the x-ray films, Dr Sosman?

DR M C SOSMAN I should say that the patient had an enlarged spleen, which displaced the stomach upward and medially A ruptured spleen is a logical diagnosis, with hemorrhage into or around the spleen, or both

DR EDWARD HAMLIN, JR I saw this patient fifteen minutes before operation At that time he had definite shifting dullness At operation the spleen was four to five times its normal size It was soft and mushy and somewhat larger than one would expect from just intrasplenic hemorrhage It was easy to remove

DR CASTLEMAN Was there a large amount of free blood in the abdomen?

DR HAMLIN A great deal

CLINICAL DIAGNOSIS

Ruptured spleen

DR MILLER'S DIAGNOSIS

Delayed rupture of spleen

ANATOMICAL DIAGNOSES

Gaucher's disease.

Ruptured spleen

PATHOLOGICAL DISCUSSION

DR CASTLEMAN The spleen that we received weighed 800 gm and contained three tears—one on the upper pole, one on the medial surface and one on the posterior aspect The largest, the one on the medial surface, was 9 cm in length and 1 cm in depth The surface was otherwise smooth The cut surface was brick red except for several well circumscribed hemorrhagic areas, measuring 1 or 2 cm in diameter, scattered throughout the parenchyma, not necessarily close to the capsule We were not able to find any really large hematomas beneath the capsule We thought that it was an ab-

mal spleen but could not pin a definite diagnosis on it grossly. It did not look like a Banti spleen, and it was not hard enough, but it did suggest the spleen of hemolytic jaundice. Sections, however, showed the characteristic histologic picture of Gaucher's disease. Throughout the pulp there were numerous large foamy slightly granular cells with

canals of the femurs and humerus are widened at the expense of the cortices. The lower ends of the femurs show the Erlenmeyer-flask deformity, which is quite typical.

DR. CASTLEMAN: This disease usually occurs in young persons. This man was thirty-one, but it has been reported in people over fifty. I believe that a

FIGURE 1 Photomicrograph of Spleen Showing the Large Number of Gaucher Cells. Note the absence of Gaucher material in the endothelial cells lining the sinusoids.

small round pyknotic nuclei (Fig. 1). The follicles were reduced in number, owing to replacement by the Gaucher cells, which, as you may recall, are reticulum cells filled with kersatin,—one of the cerebrosides. The one clue to the diagnosis was in the x-ray film of the femoral head. Dr. Schulz, will you show the films taken after the diagnosis was established?

DR. SCHULZ: The films taken after operation show deformity of one femoral head. The medullary

large percentage of the cases have occurred in Jews, and this man was a Jew.

It is possible that these bone lesions, which are produced by the Gaucher cells within the marrow and not in the cortex, may increase in number. A number of cases have been reported in which bone lesions first appeared following splenectomy.*

This patient is doing well and is about to go home.

*Pick, L. Classification of diseases of lipid metabolism and Gaucher's disease. *Am. J. M. Sc.* 185:453-469, 1933.

CASE 31522

PRESENTATION OF CASE

First admission. A twenty-year-old housewife was admitted to the hospital complaining of abdominal pain and jaundice.

About nine months before admission the patient was referred to the Out Patient Department following one positive and one doubtful premarital Hinton test. Her fiancé was Hinton negative, and she admitted no other exposure. She denied having had any of the stigmas of acquired or congenital syphilis. The patient's mother and sister had had tuberculosis,

but there was no family history of syphilis or positive serologic tests. At that time, physical examination revealed nothing remarkable. Repeated Hinton tests were positive. One Wassermann test was positive, and another was questionable. A Wassermann test on the spinal fluid was negative. The patient was started on a course of antisyphilitic therapy. She had no ill effects from bismuth, but when Mapharsen was begun she complained of nausea without vomiting beginning about half an hour after each treatment and lasting for about two hours. She had no diarrhea or itching, and the stools and urine remained normal. Neoarsphenamine was

substituted for Mapharsen and caused some nausea until the dosage was reduced, after which there were no ill effects. While under treatment she had married, and six months before entry had become pregnant. Eight days before admission she ate some fried sea food and on the following day developed a constant sharp pain in the epigastrium and right upper quadrant. Nausea developed simultaneously with the pain, and was associated with a few episodes of vomiting dark-green material. Three days before admission the pain became severe and the skin and scleras were observed to be jaundiced. She developed constipation, her bowel movements having been normal until that time. The urine became dark. She felt feverish and had a temperature of 101 to 102°F. During the following three days the pain and jaundice subsided somewhat but the discomfort in the right upper quadrant remained.

Physical examination showed a well developed, well nourished, poorly hydrated, sick-appearing woman. The skin was hot and dry. A few blotchy red spots were observed over the face and palms of the hands. There was no definite jaundice, but the peripheries of the scleras had a questionable yellowish tint. The heart and lungs were not remarkable. The abdomen revealed moderate tenderness and slight spasm in the right upper quadrant. The upper margin of the liver was at the fifth rib, and the lower margin 5 cm. below the costal margin in the mid-clavicular line. Neither the spleen nor the gall bladder could be felt. The uterus was enlarged to occupy two thirds of the distance from the symphysis pubis to the umbilicus. Fetal motions and heart sounds were present. The pregnancy was estimated to be of six months' duration. Pelvic examination revealed moderate tenderness but was otherwise negative.

The temperature was 98.6°F, the pulse 100, and the respirations 22. The blood pressure was 118 systolic, 85 diastolic.

Examination of the blood showed a red-cell count of 4,310,000, with 10.5 gm. of hemoglobin, and a white-cell count of 19,300, with 80 per cent neutrophils. The urine had a specific gravity of 1.018, subsequently ranging from 1.002 to 1.014, the sediment contained 3 to 4 white cells per high-power field. The urine gave a positive test for urobilinogen in a dilution of 1:8. One week later it was present in a dilution of 1:64, and following this it was positive three times in a dilution of 1:16. The serum nonprotein nitrogen was 21.5 mg. per 100 cc., the phosphorus 2.6 mg., the protein 5.88 gm., the albumin 3.33 gm. and the globulin 2.55 gm. (an albumin-globulin ratio of 1:3), the alkaline phosphatase 4.2 Bodansky units, and the chloride 106 milliequivalents per liter. A bromsulfalein test (5 mg. per kilogram) showed retention of 60 per cent of the dye after forty-five minutes. A cephalin-flocculation test was negative in twenty-four hours but questionably positive after forty-eight hours. The van den Bergh test was

0.85 mg. direct and 1.2 mg. indirect. The prothrombin time was 17 seconds (normal, 18 to 20 seconds).

X-ray examination of the abdomen revealed a uterus enlarged to the third lumbar vertebra. The liver appeared normal in size. No gallstones were observed.

The patient was put on a high-carbohydrate, high-protein, low-fat diet. She was given vitamins intravenously and allowed fluids up to 2500 cc. per day. She received two injections of bismuth within the fourteen days following admission. The urinary sediment continued to show a few white cells. The red-cell count fell to 3,300,000. The blood pressure, temperature and pulse remained in a normal range. At that time, a cephalin-flocculation test gave a doubtful reaction after forty-eight hours and the van den Bergh test was reported as normal. The bismuth test was reported as normal. The liver was only 3 cm. below the costal margin and was much less tender than at first. The blotchy lesions on the hands and face improved, but the scleras remained "muddy." Bismuth injections were stopped, and a course of penicillin (1,200,000 units) was substituted.

On the nineteenth hospital day, following the injection of 1500 cc. of 10 per cent dextrose in water with the addition of nicotinamide, thiamine chloride, riboflavin, Hykinone and cevitamic acid, the patient complained of weakness and blurred yellow vision. There was edema of lids, as well as chemosis and large vitreous opacities in both eyes. She had a recurrence of the anorexia, malaise and slight liver tenderness. Her face became swollen and pale. These symptoms persisted. The fetus remained normal, with a strong heart beat at a rate of 144 per minute.

On the twenty-first hospital day the patient was discharged to a lying-in hospital. The blood pressure had risen from 130 systolic, 90 diastolic, to 150 systolic, 115 diastolic, and the urine gave a + test for albumin on the last two examinations.

Final admission (two weeks later). In the interim, labor had been induced at the lying-in hospital following the development of convulsions. She was delivered of a nonsyphilitic infant who lived only twenty hours. Following delivery, the patient developed fever, leukocytosis and pyuria. Two days before admission, she had a shaking chill, associated with a white-cell count of 50,000. On the day before admission she had one episode of vomiting.

On examination the patient was pale and thin. There were a few slightly erythematous lesions on the face. The eyes showed no residual chemosis. The fundi were pale but otherwise normal. The pharynx was slightly reddened and edematous. The heart and lungs were normal. The liver was tender and extended four fingerbreadths below the costal margin. There was no true spasm of the abdominal wall, but exquisite tenderness elicited in the right costovertebral angle. The uterus was well contracted.

The temperature was 105°F, the pulse 144, and the respirations 25. The blood pressure was 100 systolic, 65 diastolic. Examination of the blood showed a red-cell count of 2,550,000, with 7.5 gm of hemoglobin, and a white-cell count of 42,000, with 67 per cent mature neutrophils, 23 per cent band forms, 8 per cent lymphocytes, 1 per cent myelocytes and 1 per cent monocytes. The red cells were hypochromic and normocytic, with moderate variation in size and shape. The urine had a specific gravity of 1.007 and gave a +++ test for albumin, the sediment contained 2 to 3 red cells and innumerable white cells per high-power field. Culture revealed abundant colonies of colon bacillus. A stool gave a ++ guaiac test. The urine was positive for urobilinogen in a dilution of 1:32. The nonprotein nitrogen was 21.5 mg per 100 cc, the protein 5.95 gm, the albumin 3.52 gm, the globulin 2.43 gm, the chloride 100 milliequiv per liter, the van den Bergh normal, and the prothrombin time 29 seconds. Repeated Hinton tests were negative in all dilutions. The cephalin-flocculation test was negative after twenty-four hours and ++ after forty-eight hours.

The patient was put on a course of intensive vitamin and carbohydrate therapy. She was treated with small amounts of sulfadiazine. The temperature responded for a few days and then rose again to 104°F. She began to vomit frequently. The urinary intake and output were poor. The liver tenderness and costovertebral angle pain increased in severity. The liver became larger, and the abdomen became distended. Peristalsis could hardly be distinguished. There was shifting dullness, without definite fluid wave. The temperature spiked at least once a day, often rising to 104°F. Pelvic and rectal examinations were negative. X-ray examination revealed hepatomegaly and a suggestion of abdominal fluid.

On the eleventh hospital day the patient became mildly disoriented. She had a chill, and the temperature spiked to 104.8°F. On the thirteenth hospital day she complained of pain and exhibited tenderness in the right groin (femoral triangle), associated with rising temperature, pulse and respirations. On the seventeenth hospital day she had generalized convulsions and was momentarily unresponsive, the trachea filled with a coarse stringy exudate but soon cleared. On the nineteenth hospital day she became incontinent of feces. The pulse was rapid and threadlike, and the pharynx was full of hemorrhagic purulent material. The temperature was 104°F, and the respirations labored and slow. The latter rapidly became slower and then ceased altogether.

DIFFERENTIAL DIAGNOSIS

DR EARLE M. CHAPMAN. This is a long story of a young mother who died at the age of twenty. I

should like to go back and reconstruct the story from the beginning as I see it.

In the first place, on the evidence of a positive serologic test for syphilis she was treated with a highly toxic agent, arsenic. I am going to raise a doubt that she had syphilis because the story is not that of syphilis. There was no evidence physically of syphilis, and there were only these fluctuating tests to indicate such disease. I think that the work of Neurath and his associates* at Duke University differentiating positive and false-positive tests for syphilis has been a valuable contribution. Their method has been a great help to me recently in differentiating these cases. Strangely enough, three of my cases have been women in the same category as this. The reports were positive, but by the Neurath method they were shown to be biologically false. This patient we are discussing today, however, was treated with arsenic, and while under treatment, it seems to me that the liver was moderately damaged, not enough to explain her death. They looked vainly by means of repeated tests to determine whether the large and tender liver was sufficiently damaged to explain the outcome. The bromsulfalein test alone was positive, the first time it was done it showed retention of 60 per cent of the dye after forty-five minutes. The dose was quite large—5 mg per kilogram. The other tests indicated little damage. It is true that she had a slight degree of jaundice in the beginning, but this can be explained by a moderate arsenical hepatitis.

When we come to the present illness, we find that she had been perfectly well until eight days before admission, when she had abdominal pain, nausea, vomiting and fever, which are signs of acute infection. This sudden episode really is the clue, as I see it, to the cause of death. The record states that she had a rash on the face and hands. Of course that may be a red herring to make us believe that it was recurring secondary syphilis or it may hint that this was lupus erythematosus, but I see nothing in this illness to fit with either diagnosis.

What organ was the one that finally failed? I do not believe, as I have said, that the hepatitis was severe enough. None of the tests fit with cirrhosis of the liver. It is clear, however, that she had kidney trouble. The specific gravity was fixed, and she had albuminuria. The development of eclampsia with convulsions during pregnancy indicates that the kidneys had been damaged. Yet she came back to the hospital and died with a normal nonprotein nitrogen, which clearly shows that the cause of death was not uremia. Although she did not die of primary renal failure, she obviously had an infection in the urinary system.

On the second admission the urinary sediment contained numerous white cells and a culture yielded abundant colonies of colon bacilli. On physical

*Neurath H et al. Serological diagnosis of syphilis. *Science* 101:68, 1945.

examination she was edematous and had exquisite tenderness in the right costovertebral angle. She then continued to have evidence of infection, — I assume she had a septic type of temperature chart, — and she failed to respond to both sulfadiazine and penicillin. When a patient dies without responding to these, there is certainly one complication that has to be considered, namely, undrained pus. None of these chemotherapeutic agents will drain a septic area, that is a surgical procedure.

DR BENJAMIN CASTLEMAN You might like to glance at the temperature chart?

DR CHAPMAN It is just as I supposed, she certainly ran a septic course. Where was the sepsis located?

Going back again, I have to consider that the first attack may have been appendicitis, a frequent disease at this age, and therefore she may have had a pylephlebitis. But the one point that I believe is against pylephlebitis is the fact that the appearance of jaundice in five days favors an intrahepatic type of disease rather than an infectious process from a pylephlebitis. Of course, it may have originally been an inflammatory reaction of the right kidney, such as a perinephric abscess, causing a toxic picture with fever and failure to respond to chemotherapy. That would fit in with the final course, since she had exquisite tenderness in the right costovertebral angle.

There is one laboratory finding that is puzzling me and I cannot fit it into the picture, that is the ++ guaiac test in the stool. The excessively high white-cell counts and the anemia fit in with sepsis arising from pus in the right kidney on top of pyelonephritis, which she had had in a mild way previously, it having been linked with the eclampsia.

Now we come to the final phase of her illness. The history states that the liver increased in size, that the abdomen became distended and that peristalsis was minimal. There again, I think that we all know that kidney disease reflexly can simulate intestinal obstruction: the bowel becomes atonic secondary to renal disease, and that fits into the pattern. Then finally she had these convulsions and was unresponsive and hyperthermia was present — all of which leads one to think of some septic metastatic process in the brain, which I can see no possible way to diagnose.

DR CASTLEMAN Dr FitzHugh, you saw this patient. Will you tell us more about her?

DR GREENE FITZHUGH We believed that the blood picture and the albumin in the urine indicated a definite toxemia, and that is why we sent her to the lying-in hospital.

Two days after the pregnancy was interrupted, the blood pressure came down and the urine cleared, we then had quite a discussion whether we should give her bismuth, since she already had a damaged liver. At that time antisyphilitic treatment with penicillin had not reached the stage where it was

generally accepted. We had considerable discussion about the diagnosis. The syphilologists thought that it was syphilis and that we had better go on with some form of antisyphilitic therapy. So we started with bismuth, but with the reports that began to accumulate on the treatment of syphilis with penicillin, we decided that we could safely shift from bismuth to penicillin.

DR JOHN L. NEWELL When this patient was admitted to the Massachusetts General Hospital she was six months pregnant. I assume that she was recovering from toxic hepatitis, which was believed to have been caused by arsenical treatment. Then she developed a rather fulminating pre-eclampsia. We know that there is no better way to aggravate a pre-eclampsia than to have large amounts of fluid given intravenously.

I did not see her at the lying-in hospital, but she must have had a rapidly progressive course. I should say from an obstetric point of view that it was fortunate that they were able to induce her at seven months. They certainly did not operate. While at the lying-in hospital, she developed pyelitis, chills and eclampsia, which are commonly associated. In fact it is considered by some men that pyelitis is the etiologic agent. It seems to me that this might have been a pyelonephritis that had progressed to a perinephric abscess and the development of generalized sepsis.

CLINICAL DIAGNOSES

Toxic hepatitis
Pyelonephritis
Syphilis, latent

DR CHAPMAN'S DIAGNOSES

False-positive test for syphilis?
Arsenical hepatitis
Eclampsia, ante-partum
Pyelonephritis
Perinephric abscess
Septicemia
Brain abscess?

ANATOMICAL DIAGNOSES

Eclampsia
Infarcts of liver, multiple
Infarcts of spleen, kidneys, lungs, adrenal gland and brain
Septicemia, terminal (*Clostridium welchii*)
Septicemia (colon bacillus)
Multiple abscesses: abdominal wound, sternum, left clavicle, liver and adrenal glands
Focal necroses in liver
Pyelonephritis, acute

PATHOLOGICAL DISCUSSION

DR CASTLEMAN On the second admission to this hospital the clinicians were not sure of the diagnosis and decided to make a small incision to find

out what was wrong with the liver. They found an enlarged liver, a biopsy showed numerous areas of necrosis and hemorrhagic infarction in the periphery of the liver lobules, findings characteristic of eclampsia. Many of the vessels were thrombosed. In other words, she still had eclampsia when she returned from the living-in hospital. That, I believe, accounted for the large size of the liver and for all the liver symptoms. Following operation she did not do well, developed sepsis in the operative wound, from which we were able to culture colon bacilli, and died in about two weeks.

At autopsy the liver infarcts were widespread, there was thrombosis of the right hepatic artery, and microscopically thromboses were seen in many of the hepatic veins. The kidneys were tremendous in size, each weighing 350 gm., which is about twice the normal weight. There were numerous thrombi associated with hemorrhagic infarction, as well as old blood within the tubules. We also found tiny thrombi in the brain, with small foci of infarction. Just before she died she developed gas-bacillus infection, by the time we did the autopsy, eleven hours post mortem, gas bubbles were grossly visible and we were able to recover the Welch bacillus from every organ. I believe that was just a terminal event, since colon bacilli had been cultured from the blood before death. I think that we can explain the entire picture on eclampsia associated with a severe renal infection.

DR. CHAPMAN: What about the arsenic?

DR. CASTLEMAN: I do not know, I suppose that a liver previously damaged by arsenic may be more prone to develop eclampsia, although I do not recall ever having heard anything said about it.

DR. NEWELL: I have never heard that.

DR. CASTLEMAN: Of course, no one knows the cause of eclampsia. A toxic agent—whatever it is that starts it off—possibly causes more damage in a diseased liver than it does in a normal one.

DR. NEWELL: I am surprised that this patient apparently recovered clinically from the eclampsia and yet had all these manifestations.

DR. CASTLEMAN: Certainly the appearance of the liver is characteristic of eclampsia. Could it have been post-partum eclampsia?

DR. NEWELL: But she did not die post partum. Death occurred three weeks after the convulsions.

DR. CASTLEMAN: She had convulsions before delivery. Did she have any afterward?

DR. FITZHUGH: She had no post-partum convulsions in the living-in hospital. She had them before she was delivered and terminally at this hospital.

DR. NEWELL: Do you think that the terminal convulsions were due to eclampsia—after two and a half or three weeks?

DR. CASTLEMAN: I do not know. She had several small lesions in the brain. Certainly the changes in the kidneys and the liver and even in the heart are those that are usually found in eclampsia, but it is possible that they were the result of the original ante-partum eclampsia.

MEDICAL CARE FOR VETERANS

THE failure of the people of the United States in the past to provide the best of medical care for veterans is inexcusable. It has been argued that such care should be limited to conditions or diseases directly or indirectly attributable to military service, but in many cases the line of distinction is difficult to draw and if there is any question the veteran certainly deserves the benefit of the doubt. Furthermore, it seems reasonable that medical and hospital care should be furnished for all veterans, without regard to the cause of their illnesses or disabilities. Now that thousands of wounded are being returned to this country, to be discharged to the care of the Veterans Administra-

tion after a certain period in Army and Navy hospitals, its facilities become of increasingly great importance, particularly since there is a possibility that the program will be extended to include the care of their dependents.

The Veterans Administration was created over twenty years ago, and in the intervening period, hundreds of millions of dollars have been turned over to it by Congress for the construction of hospitals, their staffing and their maintenance. In other words, the necessary wherewithal has been provided. Unfortunately, however, this type of medical practice has failed to attract the most competent of the medical profession.

Undoubtedly one of the reasons for this lack of appeal is the fact that physicians of the Veterans Administration are under the control and supervision of men with relatively little knowledge regarding medical matters. Three bills now before Congress (H. R. 3310 and 3317 and S. 1079) propose a department or bureau of medicine and surgery within the Veterans Administration.

Reorganization of the medical personnel along such lines would eliminate some of the difficulties of the past, but the provision that medical officers of the Army and Navy may be detailed for service in the Veterans Administration is an undemocratic maneuver that deserves little support. Rather than resort to compulsion, would it not be better to create a medical organization that appeals to the returning medical officer and to the recent graduate? Each hospital would have medical and surgical heads who are well known and competent in their particular lines of work. Appropriate salaries would be paid, and high-grade investigative work, carried out in well equipped and properly staffed laboratories, would be encouraged. In other words, these hospitals would be comparable with the modern first-class teaching hospital.

The advantages of a setup of this sort are obvious. In the first place the veteran would receive better medical care than he has ever received in the past. Secondly, medical research would be promoted. Thirdly, hospitals of this type would undoubtedly be approved for internships and residencies, and these facilities, in addition to being attractive to the recent medical graduate, would at

help considerably in the problem, as yet un-
 ed, of providing adequate means for the post-
 duate training of discharged medical officers
 d finally, the ultimate cost to the taxpayer — a
 tter that appears to receive little or no thought
 ase days — would be decreased

COSMETICS CONTAINING HORMONES

COSMETICS containing hormones are advertised
 tionally and are available everywhere for pur-
 ase without a prescription by a gullible public
 osmetics are defined as applications intended to
 eautify and improve the complexion, skin or hair
 hey are designed to make a person more attrac-
 ive, to delay (or perhaps better, to hide) the appear-
 nce of the manifestations on the skin of advanc-
 ng years, to cover defects and, in general, to make
 he skin softer and more pleasant to look on. The
 addition of hormones, which are physiologically
 active ingredients derived from endocrine glands
 or their synthetic duplicates, alters their status
 and creates a potentially serious situation. These
 beautifying preparations then become active and
 possibly dangerous and should be classed with cer-
 tain drugs, serums, vaccines, vitamins and other
 biologic products. As such they should come
 within the jurisdiction of the United States Pharma-
 copoeial Convention, the Committee on the Na-
 tional Formulary of the American Pharmaceutical
 Association or the Council on Pharmacy and Chemis-
 try of the American Medical Association. It is
 significant that none of these authorities have ac-
 cepted these hormone-containing preparations.

Extravagant claims are made of the glamorous
 results of such applications, and enormous sums of
 money in the aggregate are being spent by ill-
 advised people lured by such advertisements. There
 is, however, no satisfactory evidence that justifies
 the use of hormone-containing cosmetics for the
 purpose of local beautifying effects. The Federal
 Food and Drug Administration, as evidenced by
 a letter from Commissioner Dunbar published else-
 where in this issue of the *Journal*, is "skeptical of
 the benefits, if any, which accrue from the local use
 of these products." He adds, "We have con-

sistently informed manufacturers that because of
 the uncertainty of the ultimate effect of the use
 of these products and because of their dubious value
 we do not look with favor upon their distribution
 for lay use." On the other hand, sufficient absorp-
 tion from the injudicious use of estrogen-containing
 cosmetics to upset normal body activities has been
 demonstrated. Eller and Wolff* have recently re-
 viewed the evidence concerning the absorption of
 such preparations. In addition, the cancer-promot-
 ing properties of estrogenic substances are reason-
 ably well established. Much experimental work
 must be done to determine all the possible effects
 of a long-term use of such agents in the average
 human being, and pending such work, it is well that
 their use be carefully restricted.

The physician is seldom consulted regarding the
 use of cosmetics or their composition. He should,
 however, be cognizant of the fact that there is a
 lack of convincing data from carefully controlled
 studies to justify the lurid advertisements of the
 cosmetic manufacturers.

MASSACHUSETTS MEDICAL SOCIETY

DEATHS

DEXTER — Fred F. Dexter, M.D., of Springfield, died
 on July 10. He was in his sixty-seventh year.

Dr. Dexter received his degree from Harvard Medical
 School in 1904. Before his retirement twelve years ago, he
 was a practicing gastroenterologist. He was secretary of the
 Eastern Hampden Medical Association from 1914 to 1915.
 He was a fellow of the American Medical Association and
 a member of the Springfield Academy of Medicine.

His widow survives.

DICKSON — Richard E. Dickson, M.D., of Holyoke,
 died on May 8. He was in his seventy-eighth year.

Dr. Dickson received his degree from Jefferson Medical
 College of Philadelphia in 1895. He had served as president
 of the Eastern Hampden Medical Association and was on
 the staff of the Holyoke Hospital. He was a fellow of the
 American Medical Association.

METCALF — Richard Metcalf, M.D., of Winthrop, died
 on May 21. He was in his fifty-eighth year.

Dr. Metcalf received his degree from Tufts College Medical
 School in 1913. He was a fellow of the American Medical
 Association.

His widow survives.

REDDY — Joseph W. Reddy, M.D., of South Boston,
 died recently. He was in his seventy-fifth year.

Dr. Reddy received his degree from Harvard Medical
 School in 1896 and retired from active practice in 1940. He
 was a fellow of the American Medical Association.

CORRESPONDENCE

PHYSICIANS FORUM

To the Editor Over the years preceding, during and following my incumbency as president of the Massachusetts Medical Society I have been disturbed by what has seemed to me the lack of opportunity for the minority (perhaps the majority) of the members of the Massachusetts Medical Society to present their point of view with a reasonable chance of its receiving appropriate attention. I feel that the same situation exists in the American Medical Association. In certain instances there have even been attempts to suppress the expression of opinion of the minority. How to correct this unfortunate situation has not been clear, but recently an opportunity to improve the situation seems to have developed due to the formation and growth of the Physicians Forum, Incorporated, for the study of medical care, of which I am an active member.

This organization started in New York City a few years ago among members of a county society of the New York Medical Society, who felt that there was need for a method of expressing the opinion of the minority in organized medicine. From its meager beginning it has become a national organization, and on December 8 and 9, 1944, held in Washington, D. C., a National Health Conference on the Problems of Medical Care, which turned out to be a meeting of real significance, with fifty-one organizations represented and many individuals of prominence participating.

The Forum analyzes relevant legislation, publishes bulletins and other literature and appears before organizations of physicians as well as professional and consumers groups, and it has been called upon to advise Congressional committees.

Among other activities the Physicians Forum has now taken up the fight for the passage of the Wagner-Murray-Dingell Bill (S 1050). The Forum has been asked by lay groups interested in this legislation to assume the leadership of those members in the medical profession who are interested in this important struggle.

Although the Physicians Forum has become national in scope, it is still rather limited in membership in certain areas. Its officers believe that there are many members of the medical profession belonging to their state societies who would welcome this method of expressing a minority (or perhaps majority) opinion. The Forum also believes that there are many members of the medical profession who favor this progressive program for the delivery of medical care to the great masses of American people proposed by the Wagner-Murray-Dingell Bill but are at sea in regard to how to register their feelings.

The Physicians Forum offers such an opportunity. Its membership at the present time is limited to members of county or state societies and the National Medical Association. Those physicians who are interested in joining the Physicians Forum, or who wish to learn more of its activities, may do so by applying to me or to the headquarters of the Physicians Forum at 510 Madison Avenue, New York City.

CHANNING FROTHINGHAM, M.D.

COSMETICS CONTAINING HORMONES

To the Editor Your letter of July 6, 1945, asks what is the status of hormone-containing cosmetics so far as the Food and Drug Administration is concerned.

We have made some investigation of these products. There have been conflicting reports in the literature concerning the effects of estrogenic substances when applied locally. When applied in sufficiently large amounts there is no question but that they are absorbed and produce their usual systemic effects. When the amount of estrogens is reduced, however, to the quantity found in the products which are sold to laymen there seems to be no unanimity of opinion as to the physiologic effect. Some workers have reported the production of local edema apparently by imbibition of fluid into the collagen bundles without any systemic effect, others have claimed that it is not possible to produce a local result without at the same time causing a general one.

There has been a considerable amount of work on the car-

cinogetic properties of these materials. In highly susceptible strains of rats under very special conditions the administration of the estrogens has apparently produced carcinoma, but with ordinary laboratory animals and in all studies so far on human beings there is no evidence whatsoever that these products are carcinogenic.

We have investigated the files of a number of firms producing these products searching for evidence of injuries. We have not found such evidence.

To summarize, we have carefully reviewed the literature and consulted with many experts and, as a result of this, have arrived at the conclusion that at this time there is not sufficient legal evidence to show that the use of estrogens in the amounts found in products of this class is dangerous. We are skeptical of the benefits, if any, which accrue from the local use of these products but we do not believe that we are in a position to challenge qualified claims concerning them. We have consistently informed manufacturers that because of the uncertainty of the ultimate effect of the use of these products and because of their dubious value we do not look with favor on their distribution for lay use.

It was our plan to have conducted carefully controlled clinical studies to serve as the basis of appropriate legal action if the products proved to be worthless, but preoccupation of the medical profession with more important studies during the war and the fact that our own medical staff has been made very much smaller has not made it possible to conduct these studies. We hope that they can be made soon after the termination of hostilities.

P. B. DONNAN

Commissioner of Foods and Drugs

Food and Drug Administration
Federal Security Agency
Washington 25, D. C.

* * *

Although it is true that there is "no evidence whatsoever that these products are carcinogenic," the following statement (Nathanson, I. T. Endocrine aspects of cancer. *Am. Eng. J. Med.* 231 764-770 and 795-802, 1944) deserves serious consideration.

Strong evidence exists to indicate that endocrine factors are associated with some human tumors. There is as yet no conclusive proof that these influences are directly concerned with cancer, although an increasing number of cases are coming to light in which cancer developed after intensive estrogen therapy in organs such as the uterus and breast, which are normally stimulated by these hormones. It is probable that this is coincidence, but the association cannot be ignored. Present evidence suggests that the sex hormones are not in themselves carcinogenic. It is likely that, as a result of excessive stimulation or atypical metabolism, the tissues of susceptible persons are conditioned to the action of a carcinogenic agent. — Ed

ANTIBIOTICS

To the Editor The lack of good prefixes in Anglo-Saxon English has been one factor which has led to our pathetic and often laughable habit of making new words out of old Greek and Latin roots. The other factor is a natural instinct to hide our ignorance behind a false front of big words. Plain English words are always better than the jaw breakers that impressed our grandfathers.

Therefore a pox upon Dr. Wingo's "mycoantibiotics" and "chemoantibiotics" (a letter published in the July 19 issue of the *Journal*) and all other antibiotics. The silliness of the words is obvious when they are put into English mold against life, drug against life and so on. Why not mold germ killer or drug germ killer, if we must have novelty?

I also prefer high blood pressure to hypertension, cure or care to therapeutics, tired nerves to neurasthenia, grog shop or gin mill to liquor saloon, printing to typography, headache to cephalalgia and thousands of other plain, clear short words to their repulsive four, five or six jointed Greek and Latin equivalents. I wish more people felt the same way.

THE TREATMENT OF RHEUMATOID ARTHRITIS WITH 417 COURSES OF GOLD*

An Analysis of 259 Cases

ABRAHAM COHEN, M D,† JOEL GOLDMAN, M D,‡ AND ALFRED W DUBBS, M D §

PHILADELPHIA

MUCH has been written on the subject of gold as a therapeutic agent in the treatment of rheumatoid arthritis. Its merits are apparently undeniable, but its mode of action is still a matter of conjecture. There seems to be general agreement that gold is a dangerous drug and that extreme caution must be exercised in its administration. In this paper we wish to emphasize the matter of untoward reactions and the lack of influence of vitamin therapy on reactions as well as on treatment.

In 1943, two of us¹ reported the results of the treatment of 122 cases of rheumatoid arthritis receiving 176 courses of gold. In that report only 11 per cent untoward reactions were observed, his figure being based on the total number of courses given. Compared with the reports of other workers, this percentage was considered unusually low. The patients received, in conjunction with gold therapy, large amounts of orange juice and liver, and it was thought that one of these factors might have been responsible for the low incidence of untoward reactions.

On the basis of the above, treatment was begun with three new groups of cases. Gold was administered as in the previous study. Solganal-B Oleosum² was given intramuscularly in the following dosage: 10 mg twice weekly, 4 doses, 25 mg twice weekly, 4 doses, 50 mg twice weekly, 4 doses, and 100 mg weekly, 9 doses. This constituted a course. A rest period of at least six weeks was allowed between courses. One group received orally with the above 300 mg of ascorbic acid daily, and another group received 2 teaspoonfuls of vitamin B com-

plex three times daily. || Since most of the cases were ambulatory, it was deemed advisable to use Vitamin B complex orally in place of liver. This substance was more desirable since it permitted the elimination of another injectable preparation. A third group received gold without vitamins. Table 1 shows the number of cases treated by this method and the number of courses of gold received. We attempted by this method to determine whether one of the above factors might be considered a necessary adjunct to the treatment of rheumatoid arthritis, as well as an aid in the reduction of untoward reactions.

TABLE 1 Cases Listed according to Number of Courses and Type of Treatment

TYPE OF TREATMENT	NUMBER OF COURSES					TOTAL
	1	2	3	4	5	
Gold and vitamin C	65	35	11	6	1	118
Gold and vitamin B complex	29	16	11	8	2	66
Gold alone	43	7	5	2	2	57
Totals	137	58	25	16	5	241

As in the previous study,¹ patients were classified according to the grade of the disease and the improvement, as follows:

Class 1 Typical rheumatoid arthritis of less than one year's duration (subjective symptoms only)

Class 2 Changes in joints, with activity only slightly limited

Class 3 Changes in joints with greatly limited activity

Class 4 Dislocations, ankyloses and contractures (patient confined to bed or wheel chair)

Group 1 No improvement (NI)

Group 2 Improved (I)

Group 3 Much improved (MI)

Group 4 Very much improved (VMI)

*From the Arthritis Clinic, Jefferson Medical College Hospital and the Arthritis Clinic and Arthritis Wards, Philadelphia General Hospital.

†Chief Arthritis Clinic, Jefferson Medical College Hospital; chief Arthritis Clinic and Arthritis Wards, Philadelphia General Hospital.

‡Associate Arthritis Clinic, Philadelphia General Hospital.

§Associate Arthritis Clinic, Philadelphia General Hospital (on leave of absence).

²Gold in the form of Solganal-B Oleosum was kindly supplied by Schering Corporation, Bloomfield, New Jersey, through the courtesy of Dr. Max Gilbert.

||The ascorbic acid and the vitamin B complex (Elixir Plebez) were kindly supplied by Wyeth Incorporated, Philadelphia. Two teaspoonfuls of the latter contains 40 mg. of niacin, 12 mg. of vitamin B (thiamine) and 0.5 mg. of vitamin B (riboflavin).

The 137 patients were graded according to the severity of the disease as follows. 4.4 per cent, class 1, 29.2 per cent, class 2, 65.7 per cent, class 3, and 0.7 per cent, class 4

Table 2 shows the results of treatment in a total of 118 courses of gold administered to 65 patients in the vitamin C and Solganal-B group. Table 3 shows the results obtained in treating 29 patients receiving 66 courses of gold, as well as vitamin B complex. It was observed that patients receiving vitamin B complex reported an improvement in

gold is begun, the patient is instructed to pay particular attention to itching, rash and sore mouth. In addition, he is told that any other symptom or sign that may arise should be noted, regardless of severity and regardless of what the patient may think the cause to be. These facts are reported at the next visit and if necessary, treatment with gold is discontinued until the symptom or symptoms disappear. Thus, if a patient reports slight itching for a few hours, treatment is stopped for one week. The appearance of conjunctivitis, simple

appetite, and showed a more rapid gain in weight and a tendency toward less fatigue. The results obtained in the control group (patients who received no supportive measures), are shown in Table 4. Forty-three patients received 57 courses of treatment of Solganal-B alone.

As stated in the previous paper, we believed that patients presenting only subjective improvement should not be included among those having favorable results. Therefore, Table 5, summarizing the favorable results, includes only groups 3 and 4. According to these observations, the use of vitamins as an adjunct in the treatment of rheumatoid arthritis with gold is of little if any value.

As stated above, the previous report indicated a comparatively small percentage of untoward reactions. The steps taken to determine such reactions should be explained. When treatment with

dryness of the skin, severe headache, dizziness, pain in abdomen or diarrhea, is a good reason for interrupting treatment long enough to attempt to determine the cause.

The above symptoms, unless of reasonable severity, are not included in the category of untoward

TABLE 5 Summary of Favorable Results, according to Type of Treatment

Type of Treatment					
TYPE OF TREATMENT	GROUP 3		GROUP 4		GROUP 3 AND 4
	%		%		%

Gold alone	24	6	57	9	82

reactions. This may be one factor in the low incidence of what we consider to be untoward reaction. It is difficult to evaluate these simple symptoms but many are probably nothing more than wh

one would expect in a patient receiving no medication

Periodic blood counts and urinalyses were made. Again, we were unable to note any significant changes in the urine, except in 1 case. There were but 3 cases of severe anemia, all requiring transfusions, and when the red-cell counts were normal, treatment was resumed, one of these was fatal.

Table 6 lists the cases having symptoms severe enough to constitute untoward reactions. Eleven occurred during the first course, 8 during the second, 3 during the third, and 1 during the fourth. The incidence according to type of treatment was as follows: vitamin C and gold, 13.6 per cent (16 in 118 courses), vitamin B complex and gold, 6.1 per cent (4 in 66 courses), and gold alone, 5.3 per cent

and the sedimentation rate 145 mm (Westergren). The patient was admitted to Jefferson Hospital, where she was transfused four times with 500 cc. of whole blood at each transfusion. She was discharged after 2 weeks. At the time of discharge there was little improvement in the condition of the joints, but examination of the blood showed the following: hemoglobin 71 per cent, red-cell count 4,200,000, white-cell count 7,500, and sedimentation rate 145 mm.

The patient suffered considerably from the arthritis, getting little relief from analgesics. She received 10 mg of Solganal-B Oleosum twice weekly for four doses, 25 mg twice weekly for four doses, and 50 mg twice weekly for four doses. With each dose she received 4 units of crude liver extract. At the end of this 6-week period, she developed a stomatitis, but during treatment the improvement in the joints was dramatic. The pain and swelling completely subsided. There remained only slight stiffness, which was particularly manifest in the early hours of the morning before rising. It was originally intended that the patient should receive a full course of gold, but since a stomatitis developed, gold was stopped and crude liver extract in doses of 4 units three times weekly intramuscularly was substituted.

TABLE 6 Untoward Reactions in 137 Patients (241 Courses)

VITAMIN C AND GOLD	DOSE OF GOLD mg	VITAMIN B COMPLEX AND GOLD	DOSE OF GOLD mg	GOLD ALONE	DOSE OF GOLD mg

Anemia	540				
Course 4 (1 reaction)		Cholecystitis with hepatitis	1040		

(3 in 57 courses). The over-all incidence was 9.5 per cent (23 in 241 courses). It is obvious that neither vitamin B complex nor vitamin C in fairly large doses influenced the number of untoward reactions encountered in the treatment of rheumatoid arthritis with gold.

To emphasize the importance of caution the following case, the only fatality in the series, is given in some detail.

A B, an 18-year-old girl, was first seen on June 19, 1943 with a chief complaint of stiffness, soreness and swelling in all the joints of the upper and lower extremities. Three months previously, she had noticed on arising that her hands were stiff. She paid little attention to this, but in a few days there was swelling. Soon the elbows and shoulders were stiff and sore and it became increasingly difficult to do her work as a clerk. Two weeks after the onset of the illness, she was confined to her home. At that time there was also severe pain and swelling in the ankles and knees. The condition was progressing slowly when she was seen by one of us.

Physical examination at that time showed that the joints of the fingers, wrists, elbows, shoulders, knees, ankles, toes and cervical vertebrae were involved. There was typical uniform swelling of the fingers and considerable limitation of motion in most of the joints. The hemoglobin was 41 per cent, the red-cell count 2,700,000, the white-cell count 11,700,

After 2 weeks of treatment with liver extract only, the stomatitis began to improve, however, there was an exacerbation of the joint difficulty. The hemoglobin was 78 per cent, the red-cell count 5,800,000, the white-cell count 7,800 and the platelet count 240,000. During the following 2 weeks the arthritis was as severe as before treatment.

At the end of the 6th week, the stomatitis had disappeared but the arthritis was worse than ever before. The patient and her mother, insisting on resumption of gold therapy, were fully apprised of the serious dangers attendant on such a course. They assumed full responsibility for all eventualities and treatment was resumed with lower dosages. Twenty-five milligrams was administered at weekly intervals from October 18, to April 1, 1944. Four weeks after the new course of treatment was started improvement in the joints was again noted. The improvement continued until March 25 when the patient began to have slight pain in the joints. At that time the hemoglobin was 72 per cent, the red-cell count 3,550,000, the white-cell count 6,200, and the platelet count 260,000. Because of the slight exacerbation of pain it was decided to increase the dose of gold to 50 mg. Up to that point gold had been well tolerated. The following week, the patient presented bleeding from the gums and purpuric spots over the feet and legs. She was admitted to the Philadelphia General Hospital on April 3, with the diagnosis of rheumatoid arthritis and thrombocytopenic purpura due to gold therapy.

While in the hospital she received fifteen 500-cc transfusions of whole blood, but the red-cell count never rose above

In respect to sedimentation rates, the previous paper¹ showed that they returned to normal in only 7.3 per cent of the cases. The whole group of 259 cases shows that in 8.1 per cent of those receiving 1 course of gold, 7.3 per cent of those receiving 2 courses and 14.3 per cent of those receiving 3 courses, the sedimentation rates returned to normal. In those cases that did not return to normal after 3 courses, the sedimentation rate remained rapid even after 4 or 5 courses.

Gold is not usually administered to patients who have a normal sedimentation rate, occasionally, however, one encounters a case that responds to no other treatment, and in desperation one uses gold. Such has been the case with 9 of our patients. Of these, 4 showed excellent results and 2 were decidedly improved. One was unimproved, and 2 showed only subjective improvement. It appears, therefore, that withholding this drug from patients because the sedimentation rate is normal is not always justified. One should not hasten to use gold, however, when the sedimentation rate is normal. It should be employed only as a last resort. There were no untoward reactions in this group.

The sedimentation rates were reduced in 72.9 per cent of cases given the first course of treatment. In 35.5 per cent the rate was reduced only moderately, whereas in 37.4 per cent it was reduced by 50 per cent or more.

Thirty-three cases (12.7 per cent) showed an increase in the sedimentation rate following a single course of treatment. Fourteen were very much improved, and 5 were much improved. Thus, 19 patients showed both subjective and objective improvement in spite of an increase in sedimentation rate. Thirty-five patients showed an increase in sedimentation rate following 2 courses. Of these, 21 were both subjectively and objectively improved. Eleven cases likewise showed an increase in sedimentation rate following 3 courses, 6 patients being improved. In 7 cases the rate was increased after 4 courses, and 6 patients showed similar improvement. Although it is true that the reduction in sedimentation rate indicates favorable progress, it is also true that an increasing sedimentation rate does not always mean unfavorable progression of the disease.

It is curious that there is obvious objective improvement and apparent freedom from discomfort in these cases, yet the sedimentation rate remains rapid. We are continuing to keep a goodly number of these patients under observation to determine whether the improvement is temporary and whether the sedimentation rate is as important as we think it to be at present.

The arthritis clinics at Jefferson Medical College and Philadelphia General hospitals have been active fifteen and nineteen years, respectively. In prospect, it is with a great deal of satisfaction that we are able to make this report. For years we have stood by and observed our patients progress

from an early rheumatoid arthritis to permanent invalidism. We have removed foci of infection and have used vaccines and bacterial filtrates, both subcutaneously and intravenously, sulfur, chemicals, analgesics, physiotherapy, bee venom, snake venom, vitamins and so forth. Occasionally the effects obtained appeared encouraging, however, after continuation of one form of therapy or another a stalemate was reached. Gold therapy, on the other hand, has given us a new hope for these sufferers. We have been working with gold compounds for about five years, and consider that of all the drugs used, none have been so promising. It is true that we are not in a position to call our patients cured. There are many, however, in whom the condition has remained apparently arrested for a few years.

We are attempting to follow our cases and hope soon to report on the progress made by them. This is difficult, especially when dealing with ambulatory cases. It may be that some day more may be learned about the etiology of rheumatoid arthritis and that a specific remedy may be found. Until that day arrives, it is our opinion that gold therapy judiciously used offers the best therapeutic approach.

SUMMARY

Two hundred and fifty-nine patients with rheumatoid arthritis have been treated with from 1 to 5 courses of gold in the form of Solganal-B Oleosum, for a total of 417 courses.

The giving of 300 mg. ascorbic acid daily did not aid in the reduction of untoward reactions in 65 patients receiving 118 courses of gold.

Vitamin B complex was not a factor in reducing untoward reactions in 29 patients receiving 66 courses.

The percentage of improvement was no greater in the groups receiving vitamins as an adjunct than it was in the group of 43 patients receiving 57 courses of gold alone.

One fatality due to thrombocytopenia purpura is reported in detail. Because of objective improvement in 88 per cent of the various courses of treatment, gold preparations are recommended for the treatment of rheumatoid arthritis, but extreme caution must be exercised.

A normal sedimentation rate is not always a contraindication to gold therapy.

An increasing sedimentation rate during treatment is not always an indication that clinical improvement is not to be expected.

There were untoward reactions in 10.3 per cent of 417 courses of treatment, however, there were untoward reactions in only 8.9 per cent of 259 patients receiving a single course of gold. In the 96 patients receiving 2 courses of gold, the percentage of untoward reactions rose to 15.6 per cent.

ACTIVE IMMUNIZATION AGAINST SCARLET FEVER*

MANUEL M GLAZIER, M D †

BOSTON

THERE are a substantial number of physicians who are opposed to active immunization against scarlet fever, claiming that the accompanying reactions are unusually severe. The presence of this opposition, despite the fact that such immunization has been shown to be effective,¹⁻³ is thought provoking, and for this reason, a report is presented of the reactions in 377 private patients actively immunized against scarlet fever during the last thirteen years.

The purpose of this paper is to describe a method of active immunization against scarlet fever through use of graduated doses of scarlet-fever streptococcus toxin that was found effective both in completely immunizing against scarlet fever and in minimizing the frequency and severity of the reactions and to furnish an analysis of the resultant reactions in 340 children.

PROCEDURE

Nine patients were immunized in 1933 according to the method suggested by Dick.⁴ Five weekly injections of 250 units, 2000 units, 8000 units, 25,000 and 80,000 units, respectively, were given to each child. The series of injections was preceded and followed by a Dick test. Because of the frequency — 21 of the 45 injections were followed by a general reaction — and severity of the reactions, however, and because 4 of the patients had positive Dick tests at the end of the series, an attempt was made to increase more gradually the number of units of toxin given before reaching the final dose.

Twenty-eight patients were divided into three groups during 1933 and 1934 and immunized by means of six, seven and eight injections, respectively, given at one-week, two-week and three-week intervals. It was soon determined that the most effective method with the lowest incidence of general reactions, was that of seven consecutive weekly injections, and that method was employed in immunizing 340 children in subsequent years.

The injections were given subcutaneously in the following doses: 650 units, 2500 units, 5000 units, 10,000 units, 25,000 units, 55,000 units and 110,000 units, a total of 208,150 units. If a moderate or severe general reaction occurred, the same dose was repeated the following week. In case of an allergic reaction, the injections were stopped. Immunization was conducted during the spring or fall, preference being given to the late spring. This

was done because respiratory infections are less frequent then than at other times, which obviated the tendency of parents to blame the injections for all the infections and ailments that might develop independent of immunization.

The patient was permitted his usual regime. Recent upper respiratory infections and a history of allergic sensitivity in the patient or in the family were noted. The mother was instructed to note the reactions, both local and general. Local reactions were considered those that involved redness and tenderness at the site of the injection, general reactions included nausea and vomiting, fever, rash, itching, malaise, marked fatigue, irritability, muscular stiffness, nasal hemorrhages, pallor, cold sweats and headaches — alone or in any combination.

Immunization was confined to children over one year of age. The Dick test was given before and after the series of injections during 1935 to 1944, inclusive. If the subsequent test was positive, another series of injections was immediately begun. In the group of 72 children immunized during 1945, the Dick test was not done in the pre-school group and it was used only to test for immunity before the series of injections were given in the others.

The reactions following the seven weekly injections were carefully studied. Since local reactions rarely caused concern to the parents, only the general reactions were analyzed with reference to frequency, type, age and a history of allergic sensitivity in the patient or the family.

A special study was made of 27 children who were immunized against scarlet fever during April and May, 1939, and of 71 patients similarly immunized during the same period in 1944. All these children were immunized just after an epidemic of upper respiratory infection due to a hemolytic streptococcus had occurred in the community. A study was also made of 10 children who had been in direct contact with a case of scarlet fever just previous to immunization.

RESULTS

The general reactions were comparatively infrequent (Table 1). Of 2357 injections given, only 166 (7 per cent) produced general reactions. The most frequent of these was nausea and vomiting, rarely accompanied by diarrhea or abdominal pain, it occurred 91 times (Table 2). The children were pale, perspired freely and vomited, usually from one to three times, although some patients vomited as many as nine times. Most of these reactions

*From the Department of Pediatrics, Tufts College Medical School.
†Instructor in pediatrics, Tufts College Medical School.

occurred two or three hours after immunization. An elevated temperature was present 40 times, a rash 12, and fatigue 7. Four children had allergic reactions, and muscle pains were noted 4 times.

TABLE 1 *Relation of General Reactions to Injections*

INJECTION	DOSE UNITS	NO OF INJECTIONS	GENERAL REACTIONS NO	PERCENTAGE
First	650	340	21	6.2
Second	2,500	339	36	10.6
Third	5,000	336	33	9.8
Fourth	10,000	336	26	7.7
Fifth	25,000	335	16	4.8

Eighth (repeat)		3	0	0.0
Totals		2357	166	
General average				7.0

One child developed nasal bleeding thirty-six hours after 4 of 8 injections. Itching of the skin occurred in 2 children, headache resulted in 1, and swelling

TABLE 2 *Type of General Reaction Following Immunization*

TYPE OF REACTION	NO OF REACTIONS	PERCENTAGE OF TOTAL
Nausea and vomiting	91	54.8
Elevation of temperature	40	24.1
Rash	12	7.2
Fatigue	7	4.2
Muscle pain or lameness	4	2.4
Nasal bleeding	4	2.4
Allergic reaction	4	2.4
Itching of skin	2	1.2
Headache	1	0.6
Swelling of axillary lymph nodes	1	0.6

of the axillary lymph nodes in 1. In 28 children there was more than one reaction.

Total immunity to the scarlatinal toxin of the hemolytic streptococcus was apparently afforded in practically every case. After completing the series of injections, only 3 of the entire series of 268 patients immunized prior to 1945 had a positive Dick test, thus requiring a second series of injections. Furthermore, no case of scarlet fever has developed among these children.

The percentage of general reactions during immunization was lowest (4.7) in the youngest patients, those between the ages of one and two (Table 3). The highest rate (17.0 per cent) occurred in those

TABLE 3 *Relation of General Reactions to Age*

AGE	NO OF CHILDREN	NO OF INJECTIONS	GENERAL REACTIONS NO	PERCENTAGE
1	181	1267	59	4.7
2	36	394	35	8.9
3	35	245	29	11.4
4	15	105	9	8.6
5	15	103	8	7.8
6	13	88	15	17.0
7 to 11	25	155	11	7.1
Totals	340	2357	166	

between six and seven years old, and the next highest (11.4 per cent) in those between three and four. The rates in the other age groups ranged from 7.1 to 8.9 per cent.

In April and May of 1939 and 1944 there was present in the vicinity of Boston a mild epidemic

of upper respiratory infection due to different strains of hemolytic streptococcus. Fifteen of the 98 patients immunized at these times had a general reaction following the first injection.

Of the 10 children who had been in close contact with a scarlet-fever patient just previous to immunization, 2 had general reactions after the first injection, 5 had unusually marked local reactions, consisting of redness and swelling of the upper arm about the site of the injection, and 3 had no unusual general or local reaction.

There were 140 children who had a family or personal history of allergic sensitivity. Of these only 4 developed allergic reactions during immunization. The reactions consisted of swelling of the face, including the eyelids, nose and lips, and of the tongue, dyspnea and a maculopapular rash (2 children). In 1 child the reaction followed the first injection, and in 3 it followed the second.

DISCUSSION

The peak of positive Dick reactions in children is between the ages of one and two years, being over 90 per cent, and the incidence of general reactions during scarlet-fever immunization is lower at this age level than at any other. Because of the high percentage of positive Dick reactions in pre-school children, Bacon⁵ suggests that all children of this age be assumed to be susceptible to scarlet fever and that active immunization follow as a matter of routine, as is customary in diphtheria immunization. This suggestion was followed in the 72 children in this series immunized in 1945.

There was an interesting similarity between the percentage of general reactions in the 98 children immunized during the epidemics of 1939 and 1944 and that in the 10 children actively immunized after having been in direct contact with scarlet-fever patients. In the first series the percentage was 15, whereas in the second series it was 20. The similarity would be even more striking, 18 as compared with 20 per cent, if 3 children not included among the former are added. These children, aged one, two and four years, respectively, were given the first injection following a recent upper respiratory infection, one of them in 1939 and the other two in 1944. They developed a local reaction, with rectal temperatures of 101 to 103° F. The parents refused further immunization. In these 108 children there were seventeen general reactions following the first injection, as compared with only four general reactions following the corresponding injection in the remaining 232 children.

These reactions were not due to the presence of a nonspecific upper respiratory infection for in the spring of 1945 there was a widespread upper respiratory infection in the community. Of 72 children immunized, 31 had upper respiratory infections, however, only three general reactions followed the first immunizing dose. This suggests

that when hemolytic streptococcus infection is present in the community, a higher proportion of persons than usual are sensitive to the initial immunizing dose of scarlet-fever toxin. The work of Lancefield⁶ and Griffith,⁷ who by a precipitation reaction and an agglutination technic proved the existence of many different serologic types of streptococci associated with human infection, is pertinent in this respect. All these types may be associated with typical scarlet fever, some much more frequently than others. These same types have also been isolated from cases of septic sore throat, tonsillitis, erysipelas, otitis media and other nonscarlatinal infections.

None of the 10 children immunized after exposure to scarlet fever developed the disease. Although this suggests that the immunity response in susceptible children when given a single dose of scarlet-fever toxin after contact with the disease is rapid enough to prevent infection, such a thing seems unlikely in view of the short incubation time of the disease and the appreciable time usually required for the development of immunity.

A history of allergic sensitivity does not preclude immunization against scarlet fever in children, as shown by the fact that only 4 of the 140 patients with such a history developed an allergic reaction. Apparently the procedure of choice is to immunize routinely irrespective of sensitivity, but to stop the immunization if an allergic reaction occurs following an injection.

The reactions described in this paper may have been due either to the direct toxic action of the immunizing agent or to hypersensitiveness to some constituent of it — perhaps a nucleoprotein.

Although it was impossible to gather adequate comparative statistics, the impression was gained that the nonscarlatinal hemolytic streptococcus infections that occurred among the immunized patients were less both in frequency and in severity than they would have been without immunization.

SUMMARY AND CONCLUSION

A modified method for active immunization against scarlet fever is described. Seven weekly injections are given, which result in fewer general reactions and a higher degree of immunity than are obtained following the usual Dick method.

The incidence of general reactions was 7 per cent among 340 children between one and twelve years of age immunized during the last eleven years. The most frequent general reaction was nausea and vomiting.

Ten scarlet-fever contacts and 98 children actively immunized during epidemics of upper respiratory streptococcal infections had high incidences of general reactions — 20 and 15 per cent, respectively — following the first immunizing dose.

Immunity, as evidenced by a negative Dick test, was complete in 98.9 per cent of the children, a repeat injection being given to the others. With such a high percentage of immunity, a follow-up Dick test is probably unnecessary.

None of the 340 patients developed scarlet fever.

The best age to immunize actively for scarlet fever is between one and two years. The incidence of general reactions was lowest in this group. Since there is a scarlet-fever susceptibility of over 90 per cent at this age, an initial Dick test is not necessary.

A history of allergic sensitivity is not a contraindication to immunization.

CLINICAL NOTE

SPONTANEOUS RUPTURE OF A
NORMAL SPLEEN

REPORT OF A CASE

- HYMAN DUBY, M D *

NORTH PLYMOUTH, MASSACHUSETTS

ALTHOUGH it is difficult to accept the idea that the normal spleen can rupture under normal physiologic conditions, a relatively small number of cases of seemingly proved authenticity have been reported in the surgical literature during the last twenty years.

There are various theories adopted to substantiate spontaneous rupture of the spleen. Susman¹ has summed up the process of spontaneous rupture as follows: softening of all structures of the spleen, congestion of the portal vein and its radicles and inability of the narrower splenic vein to accommodate itself, blood thus being forced between the spleen and investing peritoneum, which finally gives way, and perisplenic adhesions which by fixing the organ predisposes to rupture. Byford² in reporting a case stated his belief that the spleen was not normal in its entirety and that the rupture occurred at a localized diseased area, which was destroyed by the hemorrhage resulting from the rupture. Rhame³ believed that the engorgement of the spleen with blood during digestion might predispose to rupture. Zuckerman and Jacob⁴ reported 20 cases of spontaneous splenic rupture. Many reported cases show disease of the gastrointestinal tract, especially of the gall bladder. Roettig et al.⁵ hold that these cases represent instances of delayed rupture, the history of trauma being overlooked, and that there may be latent periods as long as six months before rupture occurs in a previously traumatized spleen.

Spontaneous rupture of the pathologic spleen is not infrequent and has been reported from in cases of typhoid fever, leukemia, malaria, hemophilia and pregnancy. Such a case during the last trimester of pregnancy was reported to me shortly after the following case occurred:

S C (J H 30095) a 28-year-old married woman, entered the Jordan Hospital on March 9, 1944. The night before admission she was awakened by sharp pains in the upper abdomen, which interfered with breathing. The pains were not localized. She had to sit up to catch her breath, and on doing so felt cold and sweaty. Soon after this she fainted while moving her bowels, this apparently resulted in no injury. After being revived she breathed more easily but she could not move on account of the persistent upper abdominal pain. A few hours after the onset of the pain she noted pain in both shoulders. There was no nausea or vomiting. The bowels were regular. There were no urinary or other gastro-

intestinal symptoms. The regular menstrual period began on this day, without dysmenorrhea.

The past history was essentially negative. A normal delivery had occurred about 2 years previously.

Physical examination showed a well developed and well nourished woman, with a pallid skin and complaining of abdominal pain. The temperature was 100.6°F. The examination was otherwise negative except for the abdomen, which was doughy and spastic throughout, especially in the left upper quadrant. There was diffuse pelvic tenderness on vaginal examination. No masses were palpable. The consulting gynecologist, Dr M O Belson, thought that there was active intraperitoneal bleeding, probably secondary to ectopic pregnancy.

The patient was given 1 unit of plasma and prepared for laparotomy. Under ether anesthesia a low midline incision was made. There was considerable free blood in the lower abdomen and pelvis. Careful survey of the uterus, tubes and ovaries was negative. There was no bleeding from the broad ligaments. There was an ecchymotic area subperitoneally near the uterine end of the left sacrouterine ligament. This was opened and inspected, but no active bleeding was noted. It was apparent that the pelvis and pelvic organs were not responsible for the bleeding. The cecum and lower ileum and the liver were normal. On palpating the spleen it was obvious that the source of bleeding was coming from a rent in the convex surface near the upper pole.

By that time the patient was in a critical condition from loss of blood, the exploratory palpation having aggravated the bleeding. The lower incision was extended upward to the left costal margin, all clots were removed, and a splenectomy was rapidly performed, only the splenic pedicle requiring ligature. The lower incision was closed in layers, the upper incision was closed with single through-and-through cotton sutures. A rubber drain was placed in the left gutter near the splenic bed. Owing to the pulpy softness of the spleen and the haste necessary to complete the operation on account of the patient's condition the spleen was traumatized during removal.

At the close of the operation the patient was moribund, cold and pulseless, the blood pressure was not obtainable. A vein was exposed in the antecubital fossa and 1500 cc of citrated blood and 2 units of plasma were given, with good improvement.

The postoperative course was fairly uneventful. The temperature rose to 103°F the day following operation and fluctuated up to 101°F for 1 week, after which it remained normal. The wounds healed without infection. The patient received intravenous sulfadiazine, vitamin K, ferrous sulfate and liver extract during convalescence. The blood picture before discharge showed a mild secondary anemia.

The spleen was examined in the Lears Laboratory, with the following report:

The specimen consists of a spleen weighing 340 gm and measuring 15 by 10 by 4 cm. On the diaphragmatic lumbar surface there are multiple lacerations, two of the largest being situated one on either pole. The latter are jagged and measure roughly 6 cm in length. They appear to lift up the flaps of tissue. There is a small linear superficial longitudinal tear 6 cm in length in the midportion of this surface, and a deep incised laceration along one of the lateral borders extending inward 4 cm. The hilar surface presents many irregularities, with an excavation 5 by 4 by 1 cm. It is probable that this excavation represents the effects of operative trauma, and the incised and longitudinal lacerations may be similar defects. From their appearance the polar lacerations on the diaphragmatic and lumbar surfaces may well have been the result of pre-operative trauma.

On section the capsule is extremely thin, and the cortex is nodular, red-brown and extremely pulpy, with indistinct follicles and trabeculae. Microscopically the section demonstrates the usual splenic architecture, with well formed follicles and distinct sinusoids and trabeculae. There is evidence of hemorrhage in the traumatized areas.

Diagnosis: ruptured spleen.

*It is appreciated that the spleen weighed nearly twice as much as the generally accepted limit of normal. On the other hand, the reason for the increase in weight was not evident from microscopic examination nor has the patient subsequently developed a condition such as leukemia that might have accounted for the splenic enlargement.

*Surgeon Jordan Hospital, Plymouth, Massachusetts

SUMMARY

A case of rupture of the spleen is reported in which there had been no history of trauma, either recent or remote, in a previously well woman

I am indebted to Dr F J Abate for the opportunity to report this case

345 Court Street

MEDICAL PROGRESS

PRACTICAL ASPECTS OF OXALATE METABOLISM*

HAROLD JEGHERS, M D,† AND ROSEMARY MURPHY, M D‡

BOSTON

THERE are a wide variety of substances involved in human nutrition. The extensive literature dealing with the more important ones — vitamins, proteins, iron, glucose and so forth — tends to overshadow the modest literature concerning a wide range of less known and often less important substances of nutritional significance. As a result, many physicians fail to give them even a limited attention they deserve. Therefore, it is well periodically to re-emphasize subjects that are in general poorly understood.

Many common foods contain organic acids. Citric, malic, oxalic, tartaric, benzoic, lactic, isocitric, malonic, succinic, aconitic, tricarballic, salicylic, quinic and glyoxylic acids are representative organic acids found in foods. These vary widely not only in the amount and frequency of occurrence in various foods but likewise in their nutritional and metabolic significance for human beings. The papers by Smith and Orten¹ and by Mattice² may be consulted for a general discussion of this subject. Smith and Orten concisely state the problem in these words:

The presence of a number of the organic acids in mammalian tissues and body fluids has been repeatedly demonstrated. Questions therefore arise regarding the origin, possible effects and ultimate fate of these substances in the organism. Obviously, they may be derived from the preformed acids in ingested food. However, there is convincing evidence that certain acids are endogenous in origin and that they may be formed in the course of the metabolism of the carbohydrates, fats or proteins. Also, there are increasing indications that certain organic acids are not fortuitous constituents of living matter but that they are involved in definite physiological processes.

It is the purpose of this report to discuss one of these, namely, oxalic acid, which is a dicarboxylic acid with the formula $\text{HOOC}=\text{COOH}\cdot 2\text{H}_2\text{O}$. There is a considerable but widely scattered literature,

chiefly in German, French, Italian and English. Our interest in this acid was stimulated several years ago while studying a forty-three-year-old woman who had repeated attacks of oxaluria with renal colic and hematuria, with persistence of this syndrome in spite of the use of a low-oxalate diet.

OXALIC ACID CONTENT OF FOOD AND ITS RELATION TO THE AVAILABILITY OF CALCIUM

Oxalic acid is present in many foods. This represents the exogenous source of part of the blood and urine oxalates normally present in man. Table I gives data on the oxalic acid content for some representative foodstuffs, compiled from different sources.³⁻⁷ For more detailed information and for values for other foods these original sources can be consulted. The analyses by Kohman⁷ are the most modern and extensive. These reported values are of help to the physician in enabling him to prescribe a diet low in oxalic acid if it appears indicated for therapeutic purposes.

It is apparent that oxalic acid is widely distributed among the common foodstuffs. Chocolate, cocoa, tea and certain vegetables contain relatively large amounts, whereas fruits, meats and certain other foods contain little or frequently none. Of the vegetables, on the basis of Kohman's determinations, spinach, Swiss chard, New Zealand spinach, beet tops, lamb's quarters, poke, purslane and rhubarb have high contents. In contrast, peas, cucumbers, radishes, cauliflower, squash and turnip contain no oxalic acid. Most vegetables range between these two extremes.

Because the leafy vegetables serve as a valuable source of dietary calcium, much interest has been shown in the study of the effect of oxalates on the availability of calcium. In view of the prominence given by nutritionists as well as by comic-strip artists to the ingestion of spinach, it is not surprising that much of the research has been centered around this vegetable.

Most reports⁸⁻¹⁵ agree that the oxalic acid content of spinach (*Spinacea oleracea*) and New Zealand

ystals, which can be demonstrated in microscopic sections of the leaves. The calcium content also is high. It has been estimated,¹⁴ however, that the oxalate content of spinach is sufficient not only to

Experiments on rats have shown that the calcium in pure calcium oxalate supplied orally is not utilizable.¹⁵ Soluble oxalates added to the diet interfere with the utilization of calcium carbonate¹⁶ or of

calcium supplied in skim milk^{17, 18} as a result of the formation of the insoluble calcium salt. Numerous investigators^{7, 10, 11, 14-17} have demonstrated that when spinach provides the calcium content of the diet to varying degrees, calcium retention is markedly less than in similar experiments in which the source is skim milk or one of the vegetables with low oxalate content. Growth is depressed,^{7, 14} the animals appear weak and unkempt,¹¹ mortality is increased,⁷ bone and tooth development is impaired,⁷ and reproduction is unsuccessful.⁷ MacKenzie and McCollum,¹⁹ on the other hand, demonstrated that in the rat if potassium oxalate is added to an adequate diet no deleterious effects result unless the oxalate concentration is 2.5 per cent or a simultaneous deficiency of vitamin D, calcium or phosphorus occurs.

Nutritional studies on man have not been so numerous. Interest in the literature has centered chiefly in the oxalic acid content of foods and its possible adverse influence on calcium metabolism. Edelstein et al.¹² report that the calcium of spinach is poorly utilized by young infants. Bonner et al.²⁰ in a well controlled experiment showed that the addition of 100 gm. of puréed spinach or its equivalent in oxalic acid to the daily dietary of 10 growing children caused no significant variations in the nitrogen, calcium or phosphorus utilization. No toxic effects were noted during the period of the experiment. Similar findings have been reported in adults.¹³

It seems, therefore, that under conditions of certain animal experiments the calcium of spinach is nonavailable for bodily utilization and that this is related, at least in part, to the oxalic acid content of the spinach.

The Council on Foods of the American Medical Association¹³ in a detailed report on the nutritional value of spinach, summarizes its conclusions on this point as follows:

Metabolism experiments show that the feeding of spinach is of no value during early infancy as a source of calcium, there is of course, plenty of calcium in milk to meet the needs of normal infants. The evidence also shows that in young children and in adults receiving diets adequate in calcium content the inclusion of spinach does not adversely affect the calcium metabolism.

This is therefore a reasonable and practical view for the physician to take.

TOXICOLOGY

Oxalic acid is an example of a toxic substance that is consumed with impunity in small amounts in the daily food, yet when ingested in large amounts in pure form causes serious illness or death. It has considerable toxicologic interest. Knowledge of the oxalates is said²¹ to date from the middle of the seventeenth century, at which time Duclos mentioned that "salt of sorrel," or potassium oxalate, could be obtained from the plant *Oxalis acetosella*.

In 1773, Savary obtained oxalic acid from the potassium salt. In 1776, Bergmann obtained "acid of sugar" by oxidation of glucose with strong nitric acid, and this was subsequently shown by Scheele to be identical with the acid obtained from the plant *oxalis*. Oxalic acid has had various household and industrial uses, such as bleaching of cloth and straw, dyeing and calico printing, cleaning of leather and woodwork, scouring of brass and copper and removing of ink stains. It can be readily purchased in a drugstore and is widely used in industry. Druggists are required to keep a record of sales.

An acute illness or even fatal poisoning^{21 2-3} may follow the ingestion of oxalic acid or one of the soluble oxalates. Because of their extremely sour taste these substances are seldom used in cases of homicide, but they may be ingested accidentally or with suicidal intent. Their close superficial resemblance to Epsom salts has been responsible for many cases of accidental poisoning, and their availability as household bleaching and cleaning agents has made them occasional mediums for attempted suicide.

Acute poisoning is much more frequent than is chronic. Only a few cases of the latter have been reported, and it is therefore poorly understood. Hamilton²⁷ reviews 2 interesting cases. The first, described by Grolnick in 1929, was that of a painter who intermittently for a period of two years used oxalic acid in cleaning floors without protecting his hands with rubber gloves. He experienced severe pain, stiffness and numbness of the fingers. Examination revealed deep cyanosis involving the fingers and hands to the wrists, the soft tissues were tense, the skin felt cold, and the nails were yellow in color. Recovery followed treatment with hot Epsom salt soaks, dry heat and woolen bandages. The second case was reported in 1939 by Howard.³⁰ This was the case of a man whose occupation involved the cleaning of automobile radiators. In this work he boiled parts in a strong solution of oxalic acid and consequently for a period of several months was heavily exposed to oxalic acid fumes. In addition, he frequently handled oxalic acid crystals with his bare hands. His symptoms were referable to the respiratory, gastrointestinal and central nervous systems. There were a metallic taste in the mouth, marked irritation of the eyes and throat, frequent epistaxes, severe headaches, repeated vomiting, persistent cough, productive at times of fragments of tissue, melena, severe low-back pain, loss of weight, muscular weakness and albuminuria. Recovery was slow, and a state of extreme nervousness persisted for a long period.

Acute poisoning develops within a few minutes to several hours after the ingestion of oxalate. The range of the lethal doses is extremely wide, values between 2 and 30 gm. of oxalic acid having been reported. Death is undoubtedly a result not

only of the quantity of acid consumed but also of other factors, such as the form in which the oxalate is consumed, the interval between consumption and therapy, the type of treatment, the condition of the patient prior to ingestion, the renal status and the gastric acidity. Death has occurred as early as three minutes and as late as fourteen days after ingestion. The symptoms of acute toxicity may be divided into those caused by a local corrosive action and those resulting from absorption and excretion of the soluble oxalate. If a high concentration or the solid form is taken, the local effects may be predominant and death may occur without development of symptoms dependent on absorption. Immediately on ingestion there is noted an extremely sour taste, followed by a violent sensation of burning in the mouth, pharynx and region of the stomach. There may be marked dysphagia and a sense of constriction in the throat. Within a few minutes retching and vomiting occur, the vomitus is described as being coffee-ground in color or dark red. Vomiting may become intractable and be followed by severe diarrhea, with or without melena. If the condition is untreated, the vomiting and diarrhea persist and the patient may die from dehydration and exhaustion.

If death does not result from collapse associated with acute hemorrhagic gastroenteritis, symptoms develop from the systemic effects and from renal insufficiency. The former are related to the depressing action of oxalate on the blood calcium,²⁴ by which it is rendered nonavailable, and possibly to some direct toxic effect on tissue cells.

It has been estimated that approximately 0.6 gm of oxalic acid in the human blood stream at one time is equivalent to the blood calcium.⁵ The cardiovascular, neuromuscular and central nervous systems are markedly affected. The skin is pale, cold and clammy, the pulse is weak or imperceptible, and the blood pressure and temperature are low. Numbness and tingling may develop in the extremities. Cramplike muscular and abdominal pain may be extremely severe. An erythematous rash has been noted. Local or generalized muscular twitchings occur and may progress to marked tetany and convulsive seizures. The tetany of oxalic acid poisoning is due to acute calcium deficiency and can be relieved by the intravenous administration of calcium salts. The central nervous system may show evidence of excitation or depression varying from an acute maniacal state to stupor and coma. Death results from cardiovascular collapse or depression of the central nervous system.

Renal involvement is frequent and, even if the patient survives the severe local and systemic effects, may be responsible for a fatal outcome. Renal insufficiency dominates the picture from the second day.²¹ Oliguria develops and may progress to anuria. The blood nonprotein nitrogen rapidly rises. Examination of the urine shows albuminuria, numer-

ous epithelial cells, hyaline and epithelial-cell casts, erythrocytes and calcium oxalate crystals. If anuria does not develop, oliguria is followed by polyuria and hyposthenuria, which may persist for a long period. If anuria occurs early or the onset of polyuria is delayed, the prognosis is poor.

The treatment of oxalic acid poisoning consists of repeated gastric lavage with lime water, intravenous calcium gluconate or chloride and supportive therapy directed toward maintenance of the fluid balance, an adequate renal output and a normal blood pressure.

Acute oxalic acid poisoning has been reproduced experimentally in animals. MacKenzie and McCollum¹⁹ in rats, Rost³¹ and Heubner and Hüchel³² in dogs and Baudouin et al.³³⁻³⁴ in rabbits and dogs have duplicated the sequence of events that occurs in cases of human poisoning. The depression of blood calcium has been verified,³⁴⁻³⁶ and some evidence has been obtained that the severity of the reaction is controlled in part by the parathyroid glands.³⁶

Considerable attention has been focused on the pathologic lesions developing in the kidneys of animals used in experiments involving acute and chronic oxalic acid poisoning. Dunn et al.³⁷ reviewed the literature and reported their own results in rabbits. The severity and reversibility of the damage varied with the amount of oxalate injected. The kidneys were swollen, pale and edematous. Marked necrosis, especially of the proximal convoluted tubules, occurred. Although occlusion of some of the renal tubules by calcium oxalate crystals was noted, this did not appear to be an essential feature of the nephritis. Gough³⁸ studied the mitochondria of the renal tubular epithelial cells and was able to demonstrate by his technic that even quantities of oxalic acid well below toxic doses cause cellular changes, which, however, were reversible. On the other hand, as the dose is increased nonreversible necrotic changes develop, which are detectable by ordinary histologic procedures. Most authors³²⁻³⁹ agree that the glomeruli are unaffected but that the epithelial cells of the convoluted tubules become swollen and necrotic. Calcium oxalate crystals have been demonstrated within the lumens of the renal tubules as well as within the epithelial cells. Heubner and Hüchel³² noted that at autopsy the *testes* showed the largest oxalate content of any organ and that examination of tissue sections by means of polarized light showed a wide distribution of crystals throughout the kidney. Koch²⁴ in a study of the kidneys of a fatal human case also was able to demonstrate intracellular oxalate crystals. Attempts to produce macroscopic oxalate calculi have not been highly successful. Rost,³¹ however, reported oxalate concretions in the calyces of the kidneys of three dogs fed sodium oxalate for several months and Kevser⁴⁰⁻⁴¹ was able on a few occasions to produce renal calculi in rabbits after

the administration of large amounts of butyl oxalate with calcium chloride or oxamide

Koch²⁴ concluded from his experiments that the type of renal damage depends on a number of variables, the most important of which is the nature of the oxalate excreted. Thus, if sufficient oxalic acid or soluble oxalate reaches the kidney a necrotizing nephritis may result, whereas if absorption has been slow and sufficient time has elapsed for complete combination with calcium, the results depend on the hypersecretion of a normal urinary constituent

RHUBARB POISONING

From time to time there have appeared in the medical literature references to episodes of acute illness following the ingestion of rhubarb, particularly the leaves, and certain other foods—for example, sorrel⁴²⁻⁵⁰. The knowledge that such food-stuffs have a high oxalic acid content has invariably led to the incrimination of oxalic acid as the toxic factor in these cases. For instance, Widmark and Ahlén⁵ report that the stalks of rhubarb plants contain 0.39 to 0.51 per cent oxalic acid, whereas the leaves contain only 1.2 per cent. Other authors report comparable values

Beattie,⁵¹ in this country, in a government pamphlet issued in 1937, discussed this problem in these words

The succulent acid leafstalks of rhubarb make most excellent sauces and pies, and the question often arises about the use of the leaf blades for greens. Numerous cases of more or less serious illness and some fatalities have been reported in both Europe and in North America from eating rhubarb leaves. These leaf blades were eaten boiled in the belief that they were a suitable substitute for the common greens, but owing to the high content of oxalic acid and its soluble salts found in rhubarb leaves it is recommended that they be left entirely alone and not used under any circumstances as food. In the stalks, however, the oxalic acid is present in smaller amount and largely in insoluble form, and for this reason is harmless

This subject has also, in recent years, received editorial comment in the *Journal of the American Medical Association*⁵²

As reported in the literature the symptoms of rhubarb poisoning varied greatly. In mild cases the symptoms are those of a gastroenteritis, with abdominal pain, vomiting—occasionally with hematemesis—and diarrhea predominant. In severer cases, hemorrhagic diathesis, kidney, hematuria, convulsions, collapse, and coagulability of the blood and coma have been noted. At times, genitourinary symptoms—renal colic with hematuria—without gastrointestinal manifestations have been observed

Almost all the reported cases are in the earlier literature. Many occurred in England during World War I, at which time it had been suggested by various newspapers that rhubarb leaves be used as a vegetable substitute. The role of oxalic acid in some of the reported cases of rhubarb poisoning

is open to question. At times the amount of rhubarb consumed scarcely seemed likely to contain enough oxalic acid to be poisonous. Kohman¹ refers to an investigation by Maue in which he and five other men repeatedly ingested cooked rhubarb leaves with no toxic effects whatsoever. Other reports indicate that a food rich in oxalic acid was responsible for death or illness.⁵⁰ In one case death occurred after ingestion of half a peck of cooked rhubarb leaves and part of the water in which it had been cooked.⁵⁰ On investigation of an outbreak of "ptomaine poisoning" following the ingestion of soup of sour grass (sorrel), a public health official found that the soup contained about 0.13 per cent oxalic acid. The precise minimal amount of oxalic acid necessary to produce symptoms is not known, and perhaps varies with individual susceptibility and gastric acidity

It is well to remember that the gastroenteritis of food infection may readily simulate mild oxalic acid poisoning, and conversely that the abdominal pain, vomiting and diarrhea due to the ingestion of oxalic acid may simulate the gastroenteritis or gastritis of food infection. Since some skepticism has been expressed about this subject, physicians who encounter suspected cases of rhubarb poisoning could make a worth-while contribution to the medical literature by reporting cases that have been carefully studied by modern chemical and bacteriologic methods. There is a distinct paucity of reliable information on this subject in the modern literature

It is known that ingestion of an ordinary portion of cooked rhubarb stalks may cause an increase in the urinary excretion of oxalate.⁴⁴ In a susceptible person this may occasionally be the contributing factor in the production of clinically significant oxaluria. There are a number of reports of hematuria attributed to the ingestion of rhubarb.^{47, 48}

THE SYNDROME OF OXALURIA AND OXALEMIA

The identification of crystals of calcium oxalate in the urine by Donné in 1838 stimulated interest in their clinical significance. Within the following decade attempts were made to correlate the presence of the crystals with the occurrence of definite symptoms and signs, and under the influence of Prout, Golding Bird and Begbie,⁵⁴ there emerged the concept of a so-called "oxalic acid diathesis." Subsequently an extensive literature developed and such terms as "syndrome of oxaluria," "oxalemia," "oxalic acid diathesis" and "oxalic gout" became diagnostic scrap baskets. The German literature is conspicuous for the paucity of reports on this subject. A few papers have appeared in the English and American journals, but the greatest source of information has been the work of French and Italian investigators, who, it would seem, have been unduly influenced at times by the great European spas

The terms "oxalemia" and "oxaluria" refer to a state in which the oxalic acid levels of the blood and urine respectively are elevated above normal. Such elevated values have been reported in a wide variety of diseases, for example, diabetes, acute and chronic renal insufficiency, cirrhosis of the liver, nutritional deficiencies and cardiac failure. In addition to these well-recognized clinical conditions, oxalemia and oxaluria are said to be found in association with a variety of symptoms and signs that, grouped together, have been considered as a specific syndrome. The variations in the manifestations of this syndrome are numerous. It may mimic an acute abdominal crisis or biliary or renal colic, it simulates gastrointestinal or genitourinary disease, it presents itself as a disease of the muscles or joints, or it manifests itself as a disease of the central nervous system.

Neville⁵⁵ and Goffon and Nepveux⁵⁶ refer to a constitutional diathesis associated with the syndrome. The patient is irritable, depressed, anxious, hypochondriacal, dyspeptic and neurasthenic. In addition, he may show periodically one or any combination of the following clinical pictures.

The gastrointestinal tract may be, and frequently is, the site of greatest disturbance.⁵⁷⁻⁶⁰ There may be epigastric distress after eating, diarrhea alternating with constipation, severe gastric crises with retching, vomiting, even hematemesis and spasmodic intestinal pain, which may be accompanied by the passage of calculi or blood from the rectum. The vomitus has been reported to contain calcium oxalate crystals.⁵⁷ The abdominal pain may be extremely severe and associated with signs of an acute intestinal obstruction. A description of 2 such cases, one of which was subjected to abdominal exploration, was reported by Rawling.⁶¹ These, however, appear to have been cases of oxalate lithiasis with marked gastrointestinal symptoms and need not be designated as a special syndrome.

A second manifestation of the syndrome is renal in nature. The literature contains a number of reports of severe renal episodes thought to be examples of the syndrome.⁶²⁻⁷¹ In general, the picture is that of severe renal colic, either unilateral or bilateral. There is pain in the flank, which may radiate to the genitalia, frequency, urgency, burning on urination, cystalgia and gross and microscopic hematuria. Reflex gastrointestinal symptoms—vomiting, abdominal distention and so forth—may occur. The episodes are paroxysmal and at times appear to have a tendency toward a seasonal recurrence, being most prominent during the summer. In some reports this has been attributed to the consumption of such foods as rhubarb, spinach, tomatoes, strawberries and gooseberries, foods thought to be rich in oxalates, others attribute it to the precipitation of calcium oxalate crystals because of concentration of the urine during the warm weather. Most of the reported assays, how-

ever, fail to confirm high oxalate values in any but the first two mentioned foods. Examination of the urine at the time of the attacks reveals a heavy concentration of calcium oxalate crystals, irritation from which is the explanation for the pain and hematuria. Roentgen-ray and cystoscopic examinations have been negative in the cases in which studies have been made. The symptoms are said to disappear when the patient is maintained on a low oxalate diet and fluids are forced. The renal manifestations of the syndrome appear to be the best substantiated. The most modern support to the theory that oxaluria may produce symptoms has been given by Black.⁶⁸ Oxaluria with symptoms—chiefly colic and hematuria—occurred in 43 men and was the most frequent urologic condition requiring hospital admission among soldiers from a British division training in India. In this study oxaluria was not diagnosed until a full investigation—cytologic and bacteriologic examination of the urine, cystoscopy and intravenous or retrograde pyelography—had been carried out to exclude other causes for these symptoms. Black also presented some cases suggesting that oxaluria with epididymitis may be a distinct entity.

Loeper,⁷² Loeper et al.⁷³ and Violle⁵⁹ use the term "oxalic acid gout" to designate a condition in which the oxaluric diathesis is accompanied by symptoms and signs associated with the muscles or joints. They claim that patients with this ailment have oxalemia with a variety of findings, for example, migraine headaches, psychasthenic depression, vague pains, hypotension, gastric and intestinal crises, mucous colitis, intestinal and renal lithiasis and hematuria. In addition, they have severe chronic rheumatism and arthritis and may develop a tophaceous type of "gout." The rheumatism is described as an afebrile, slowly progressive, chronic disease. There are vague pains in the extremities and fingers, with crepitation of the knees and shoulders. Enlargement of the ends of the phalangeal bones occurs, and knotty deformities the size of lentils may develop on the lateral aspects. Sometimes mild dislocations occur. On roentgenologic examination the bones appear to be rarefied, and there is thickening of the periarticular tissues, deformities of the phalanges and erosions of the ends of the bones. The tophi, when present, are aberrant, juxta-articular or articular in location. It is thought that originally the tophi are primarily pure calcium oxalate, but that eventually they change to calcium carbonate or are followed by the precipitation of cholesterol and uric acid so that mixed tophi result. Loeper⁷² claims that the administration to a patient of this type of calcium oxalate or foods rich in oxalates causes an exacerbation of the symptoms.

Grott⁷⁴ reported 4 cases of acute arthritis clinically indistinguishable from acute gouty arthritis. When the patients failed to respond to the routine therapy for gout, determinations of blood uric acid

and oxalic acid showed the former to be normal and the latter elevated. Clinical improvement followed administration of diets low in oxalates. Dietary indiscretions were frequently followed by exacerbations of symptoms. Grott concluded that some cases of gouty arthritis are related to disturbances in oxalic acid metabolism rather than to those in uric acid metabolism. This concept has not been confirmed.

Cohen and Reid⁷⁶ reported 7 cases of tenosynovitis crepitans involving the flexor and extensor tendons of the wrist. Although it was true that in most cases mechanical strain appeared to be a precipitating factor, oxaluria occurred in every case, and in 3 cases there was in addition a history of urinary lithiasis. There was no response to the usual therapy until a regime of low-oxalate diet, alkalization and increased intake of magnesium was instituted.

Laroche⁷⁶ has summarized the clinical picture of oxalemia with involvement of the central nervous system. Asthenia, melancholia and vague pains have been noted. Migraine attacks are frequent. Intercostal, crural, sciatic and brachial neuralgia may predominate. Convulsive seizures have been reported by Rodillon⁷⁷ in patients whose spinal fluids contained crystals of oxalic acid. Finck⁷⁸ reported the case of a patient with severe headache and the signs of marked meningeal irritation. The condition persisted until the onset of hematuria associated with marked oxaluria, following which the neurologic picture completely disappeared.

In its complete form this syndrome apparently mimics a wide variety of clinical pictures. The mechanisms suggested to explain it are largely speculative and, except for the renal phase, remain for the most part as obscure as the so-called "facts" related to the intermediary metabolism of oxalates.

The syndrome of oxaluria with colic and hematuria is often mentioned in the American literature and in textbooks on urology. There appears to be a growing appreciation of the fact that renal colic and hematuria may result from the passage of crystals or microscopic aggregates of crystals as well as from macroscopic stones. For example, sulfonamide therapy may give rise to it. Less known but well described in the literature is the syndrome of uric acid showers with renal colic.⁷⁹⁻⁸¹ Uric acid crystals may precipitate out, irritating the renal pelvis and ureter and producing colic. They redissolve before voiding. The patient passes very acid urine, generally clear of crystals but containing red blood cells. If the urine is allowed to stand for twenty-four to seventy-two hours in a sterile test tube, crystals precipitate on the glass and on tapping the tube rain to the bottom and may be collected for microscopic and chemical analysis.

A large municipal hospital like the Boston City Hospital receives many emergency admissions for renal colic. We have been impressed over the

years with the frequency with which the standard K U B (kidneys, ureters and bladder) roentgenogram and routine pyelogram, when used alone, fail to demonstrate a calculus or to establish the cause of the colic. It is well for the physician to keep in mind that the clinical picture of renal colic without a demonstrable calculus on a K U B roentgenogram may be due to a non-shadow-producing calculus or mass, — uric acid, fibrin or blood clot, — Dietl's crisis, sulfonamide lithiasis, oxaluria, syndrome of uric acid showers, possibly the passage of excessively concentrated urine and so forth. Patients admitted to a hospital for renal colic should be instructed to void each specimen of urine into a urinal through a piece of cloth. Not only does the recovery of some gravel or a stone establish the diagnosis, but chemical analysis indicates the nature of the calculus and enables the physician to plan a more rational method of therapy. Urine voided during or shortly after an attack of colic should be examined for crystals as well as other sediment, the specific gravity and the pH. Red blood cells disappear if urine stands too long or is too dilute. If the urine is extremely acid a specimen in a sterile test tube should be set aside for precipitation of uric acid crystals. A chemical test for cystinuria, the Sulkowitch test for hypercalciuria and culture of urine for urea-splitting organisms are well within the scope of any hospital laboratory. These procedures often enable the cause of renal colic to be established when calculi are not detected by roentgen-ray study.

(To be concluded)

CASE 31331

PRESENTATION OF CASE

A fifty-nine-year-old woman was admitted to the hospital complaining of a mass in the abdomen.

Ten months before admission the patient noticed, after reaching forward, a sensation of heaviness in the abdomen occurring about once a month and followed on one occasion by watery diarrhea. Four months later, while lying on her right side, she detected a mass in the left flank that progressively increased in size but caused no symptoms, except a sensation of weight, at times it seemed to pulsate. Two months before admission she had an attack of low back pain, which radiated upward and was severer than the back pains that she had had for many years. During this period she worked hard and became weak, tired and dyspneic, after a period of rest these symptoms disappeared.

The past history was noncontributory except that she had been jaundiced for one month thirty years previous to admission.

On examination the patient was a well developed, moderately obese woman in no acute discomfort. Multiple subcutaneous nodules were palpable over the arms and thighs. The heart and lungs were normal. In the left upper quadrant of the abdomen was a firm, moderately tender, irregular mass about 10 cm in diameter. It descended with inspiration and was movable on pressure in the left costovertebral angle. Peristaltic sounds were heard in the region of the mass. Pelvic and rectal examinations were negative.

The temperature, pulse and respirations were normal. The blood pressure was 125 systolic, 80 diastolic.

Blood examination showed 14.9 gm of hemoglobin and a white-cell count of 7400. The stools were negative for occult blood. The nonprotein nitrogen was 15 mg per 100 cc, and the fasting blood sugar 100 mg. The total serum protein was 6.1 gm per 100 cc. The serum amylase was 36 units per 100 cc. All urine specimens were negative.

A barium enema done ten days before admission showed passage of barium from rectum to cecum without delay. There was reflux into a normal

appearing terminal ileum. No constant filling defect, ulceration or diverticulum was seen in the colon. The ascending colon and cecum were twisted on themselves so that the tip of the cecum lay in essentially the same position as the hepatic flexure. The palpable mass in the left upper quadrant was not attached to the bowel (Fig 1). It displaced the splenic flexure laterally, and the transverse colon inferiorly. The palpable mass was distinctly seen on the film. It measured 10 cm in diameter. The stomach appeared to lie medially to the mass and above it. The spleen was not visualized. A small bowel enema showed the mass to lie in the left upper quadrant, between the stomach and transverse colon, displacing the stomach upward and the transverse colon and upper small intestine downward. An intra venous pyelogram was negative. A gastrointestinal series was negative.

On the ninth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR MERRILL C. SOSMAN†: I should like to have more details about the nodules found over the arms and thighs. How large were they? Were they freely movable? What was their distribution? Was there any pigmentation associated with them? I assume that they were neurofibromas.

DR BENJAMIN CASTLEMAN: There is no further information recorded. I should agree that they were probably neurofibromas.

DR SOSMAN: "The heart and lungs were normal." I assume that statement was based on the usual method of examination with the stethoscope, which is not reliable in spite of what one of your doctors said at one of these meetings several months ago. Since there are no x-ray films of the chest, we must accept the opinion, but not as a fact.

The serum amylase was 36 units per 100 cc. At the Peter Bent Brigham Hospital anything up to 100 units is normal. This was well below the border line of abnormality.

Submitted with this protocol was this series of x-ray films. There are several facts that can be determined from the x-ray studies, and opinions can be deduced from these facts. I think that we should carefully separate the two. First there is a barium enema, then a small-bowel study, then intravenous urograms, and finally, a gastrointestinal series. I was a little intrigued in going over these films to find that all of them have the same identifying number but one. I assume that you have a unit number for these patients, and I wonder if this film belongs to the group.

DR DEAN CRYSTAL: The patient was seen in the Out Patient Department and given a number, and was then transferred to the house and given another

†Clinical professor of radiology, Harvard Medical School, radiologist, Peter Bent Brigham Hospital.

*Case records of the Massachusetts General Hospital (Case 31322). *New Eng J Med* 232:353-358, 1945.

number before it was realized that she was the same patient

DR SOSMAN We can check that statement by observing the details of the spine — the intimate, personal, private anatomic details. As a matter of fact, x-ray films are a good method of identifying persons during life and even after death, and they have frequently been used for that purpose. If one compares the transverse processes, the articular facets

upward. There is a large vacant area here, which spreads the duodenal loop. It looks as if the mass had moved to the right side. I cannot tie that up with the examination when it was said that the mass was in the left upper quadrant. I should like to ask if the mass moved.

DR LAURENCE L. ROBBINS Dr H. P. Mueller, who did the fluoroscopy, — in fact, I believe that he interpreted all the films, — was certain that each

FIGURE 1 Roentgenogram of the Abdomen Showing the Soft-Tissue Mass in the Left Upper Quadrant

and the details of the fourth and fifth lumbar vertebrae in these films one finds that they are identical, so that the statement is correct.

The outline of the mass is best seen in this film of the kidney and bladder region, which preceded the intravenous urogram. There is a fairly sharply outlined mass in the left upper quadrant, which also shows well in the barium-enema film. The protocol states that the mass was irregular to palpation, whereas the shadow on the x-ray film is smooth and distinct in outline, making it look like a cystic mass. I agree, however, with the report that the first barium enema was normal. There is no evidence that the tumor arose from the colon. The stomach is displaced

time he examined the patient the mass was in a different part of the abdomen.

DR SOSMAN So it was a freely movable mass, and I assume that the mass in the right upper quadrant below the antrum of the stomach, lying above the colon and distending the duodenal loop (Fig 2), is the same one that we saw in the left upper quadrant (Fig 1).

The intravenous urogram is essentially normal, except that the upper calyces of the left kidney are not well filled. There are two small areas of calcification that might be interpreted as the tips of these calyces, since they are in proper relation to the outline of the kidney. As a matter of fact, the

two shadows are present in the plain film before the intravenous urogram was made. I assume that these two small calcified areas were in the mass and were not part of the kidney.

Finally the gastrointestinal series shows a well filled stomach, with normal mucosa and normal peristaltic waves, and a normal duodenal loop. I consider this jejunal loop to be abnormal. It is a little too large, and the rugae on the left side adjacent to the mass are not entirely distinct. Going back to the small-bowel examination, I see a loop

it would probably have to be a large benign cyst) a cyst in the tail of the pancreas and, finally, an ovarian cyst with a long pedicle. These are the five major considerations. I believe that we can rule out the spleen because the tumor does not displace the colon in the usual manner. An enlarged spleen almost invariably displaces the splenic flexure downward and medially, whereas here the mass lies medial to the splenic flexure. If it is spleen, it would have to be an aberrant spleen, and presumably a tumor of an aberrant spleen.

FIGURE 2 Roentgenogram Showing the Mass Displacing both the Barium-Filled Stomach and the Colon
The mass has migrated to the right of the spine

of small bowel that I think is larger than one ordinarily sees.

To sum the whole thing up, the patient came in with a mass in the left upper quadrant, and after nine days of hospital study the diagnosis was still a mass in the left upper quadrant. I do not believe that there is any evidence here to indicate the exact origin of the mass. From these examinations, however, we do know that it was not a part of the stomach and that it did not arise from the colon, if this dilated loop of small bowel means anything, it could have arisen from the wall of ileum. We have to consider, then, a tumor of the small bowel, a mesenteric cyst, a tumor of the left kidney (with no more distortion of the renal pelvis than we have here,

Going back to the small bowel and jejunum, there are four or five conditions that are commonly found there. One is reduplication, which almost always is found in children. I believe that it is quite rare to see it in a woman of fifty-nine. Then there are the sarcomas, — leiomyosarcoma and spindle-cell tumors, — but in such cases there is almost invariably a history of ulceration and hemorrhage. This patient had no anemia and no blood in the stools. The episode of weakness, fatigue and dyspnea could have indicated a massive gastrointestinal hemorrhage, but she failed to notice tarry stools. Lymphoma is frequently found in the small bowel, but that also is likely to cause hemorrhage, although not so often as the spindle-cell sarcoma, further

ore, there is usually evidence of the disease elsewhere. Finally, we must consider a neurofibroma arising in the wall of the bowel or one of the nerves in the mesentery. She had subcutaneous neurobromas, but I do not remember ever having seen a large neurofibroma in the abdomen. This is still a possibility in spite of that.

Mesenteric cysts are fairly rare. A cyst of unknown etiology with chylous fluid or serous fluid is occasionally seen. And there are the so-called "enteric cysts", the pathologists give them this name, but they are probably the same as the reduplications that they talk about at the Children's Hospital. There are also the extremely rare nephrogenic cysts, which occur in the bowel remnants of the wolffian body, and a dermoid cyst, not associated with the ovary, is occasionally found. In fact, the two areas of calcification are suggestive of the latter.

I do not believe that it was a cyst of the pancreas because it was so freely movable and because of its location. It could have been a cyst of the ovary with a long pedicle, and that might account for the severe attack of pain in the back radiating upward, assuming that the previous ones that she had had many times were from the same cause. That would nicely explain the pains — torsion of an ovarian cyst with a long pedicle.

After looking over all these possibilities, I have no particular opinion concerning what it really was. I have ruled out a good many things, but there are still some even more remote possibilities, such as carcinoid of the small bowel or argentaffin tumors. These are found in association with multiple neurofibromas, but the carcinoid or argentaffin tumor is extremely small and rarely undergoes cystic degeneration, in all probability it can be ruled out. I have narrowed the field down to two main possibilities — ovarian cyst with a long pedicle and enteric cyst in the wall of the small bowel. Ovarian cyst must be considered, particularly because of the remarkable mobility of the mass. I believe that we can rule out cyst of the kidney. If this is the same tumor on the right, we can rule out cyst of the pancreas. I shall have to make a double-barreled diagnosis, so to speak, instead of pinning all my faith on a single one, that is, enteric cyst or ovarian cyst.

DR ROBBINS: We followed the same line of reasoning as Dr Sosman. I do not believe that we were impressed with the appearance of the jejunum. Dr Mueller said that during fluoroscopy the jejunum appeared to be normal. I thought that it probably was a cyst in the gastrocolic ligament because of the way it so consistently maintained its relation to the colon and stomach.

CLINICAL DIAGNOSIS

Pancreatic cyst.

DR SOSMAN'S DIAGNOSIS

Enteric or ovarian cyst

ANATOMICAL DIAGNOSIS

Multilocular cystoma of pancreas

PATHOLOGICAL DISCUSSION

DR CASTLEMAN: Dr Crystal, will you tell us what you found at operation?

DR CRYSTAL: We found a large tumor with a granular surface pushing the gastrocolic ligament forward. It proved to be a huge multilocular tumor of the neck of the pancreas, the portion that lies to the left of the notch for the mesenteric vessels. A small part of the mass was attached to the region just to the left of the mesenteric vessels. It could

FIGURE 3 Photograph of a Cross Section of the Specimen

not be dissected free from the pancreas, and yet it appeared to be an encapsulated benign tumor. It was possible to transect the pancreas in two places, one just to the left of the uncinate notch and the other just to the left of the tumor, at a distance of about 5 cm, and to lift the tumor out, preserving intact the splenic vessels, which we did not have to tie. The question then rose whether or not we should remove the tail of the pancreas and the spleen along with the tumor. We elected to leave the pancreas and spleen, the latter was done because of our observation on several occasions that incidental removal of the spleen has been followed by thrombosis of the splenic vein.

The patient has done well. I do not know whether she will develop a pancreatic fistula. She has had fever every day, and I imagine that a fistula may eventually appear, possibly lasting for several months.

DR CASTLEMAN: The mass that we received was well encapsulated and quite nodular, but the nodules were smooth, not granular such as one may

see in ovarian carcinoma. These nodular areas were translucent, pinkish and gelatinous, being quite similar in appearance to the thyroid tissue. A cross section of the tumor revealed varying sized multilocular cysts filled with viscid gelatinous semisolid material resembling colloid (Fig 3).

Histologically one section showed a bit of pancreatic tissue separated from the tumor by a thick

FIGURE 4 Photomicrograph Showing the Cystic Spaces

capsule. The mass was made up of cysts of varying sizes, separated by fibrous connective tissue (Fig 4). The lining of these cysts was flat to low cuboidal epithelium, and occasionally there was a suggestion of papillary projections. This is the appearance that we have seen a number of times in so-called "cysts of the pancreas." I believe that the lining is epithelial, although it is conceivable that it is endothelial, the tumor being a form of lymphangioma. Although they are often called "cystadenomas," I prefer the term "cystoma" because they really do not form glands. They are simply spaces with single layers of epithelium, occasionally high and with a papillary arrangement. There was no evidence of malignancy.

CASE 31332

PRESENTATION OF CASE

A forty-nine-year-old woman was admitted to the hospital complaining of dyspnea and a sensation of pressure over the sternum.

During the year before admission the patient had had a marked decrease in appetite and had lost 20 pounds in weight. During the same period her teeth had rapidly become carious. Six months before entry she first noted swelling of the ankles and feet, worse at night and accompanied by aching from the hips downward. Exertional dyspnea soon developed, and she became easily fatigued. Early

in her illness she complained of pain in the shoulders and arms, usually on the right but sometimes on the left. She consulted a physician, who found albumin in the urine. At that time the red-cell count was 5,000,000. Weakness and fatigue progressed, and she became extremely pale. The red-cell count was found to have decreased to 2,000,000. Liver and iron were given, with improvement of the pallor but not of strength. For nine weeks before admission she was confined to bed. Each evening there was a low-grade fever, the highest temperature recorded being 101°F. Chest plates taken two months before admission were said to have shown healed tuberculous lesions in both lung fields. Two days before admission the patient first experienced an attack of breathlessness, with a sensation of extreme sternal pressure from the xiphoid to the sternal notch, tickling in the throat and a dry spasmodic nonproductive cough, accentuated in the sitting position. There was no chest pain. These symptoms persisted, and respiration was difficult. Orthopnea appeared, with palpitation and sweating. She could not sleep well, and sedatives had been given.

Before the onset of her illness the patient's health had been excellent. One brother had died of tuberculosis, and another brother and a sister had active tuberculosis at the time of the patient's admission.

Physical examination revealed a markedly pale, acutely ill, apprehensive woman, gasping for breath. Purplish blotches were seen about the wrists and ankles. The pupils and fundi were normal. The teeth were markedly carious, with pyorrhea. The tongue was smooth, with no lesions. The cervical, axillary and inguinal nodes were firm, shotty and nontender. The thoracic cage was poorly developed, and the xiphoid depressed. Breathing was chiefly abdominal, without lag or retraction. Over the right upper chest, posteriorly, tenderness was elicited and expiratory wheezes were heard. The mediastinum was widened, extending 15 cm on each side of the midline. The point of maximum cardiac impulse was 8 cm to the left of the midline. A harsh systolic murmur was heard over the entire precordium. The abdomen was spastic. The edge of the liver was percussed four fingerbreadths below the right costal margin, but satisfactory palpation was impossible. The spleen could not be felt. The reflexes were physiologic.

The temperature was 100°F, the pulse 100, and the respirations 25. The blood pressure was 210 systolic, 100 diastolic.

Examination of the blood showed a red-cell count of 2,090,000, with 51 gm of hemoglobin, and a white-cell count of 13,100, with 85 per cent neutrophils, 7 per cent lymphocytes, 5 per cent monocytes and 3 per cent basophils.

X-ray examination of the chest showed an extensive old tuberculous process, there were mottled areas of increased density and interspersed fibrosis occupying the upper two thirds of both lung fields and

extending into the right lower lung. There seemed to be a cavity in the right upper chest, and probably many small areas of cavitation in both upper lobes, the so-called "bronchiectatic changes" of long-standing tuberculosis. The remaining, better ventilated portions of the lung showed a hazy increase in density.

The temperature varied from 100 to 101.5°F, falling to 97 terminally. The patient went downhill rapidly and expired on the third hospital day.

DIFFERENTIAL DIAGNOSIS

DR WILLIAM W. BECKMAN: There are probably two unrelated parts to this illness—first, the pulmonary disease, which was apparent by x-ray examination, and second, the remainder of the illness—the debility, the edema, the albuminuria, the rapidly progressing refractory anemia, the hypertension and the terminal episode, which is consistent with left ventricular failure in a hypertensive heart. That train of events led me to believe that it was necessary to make a diagnosis of nephritis. The question is what kind of nephritis. One can fairly well rule out malignant hypertension by the fact that the eyegrounds were normal. Between chronic glomerulonephritis and chronic pyelonephritis it is impossible to differentiate without more information regarding the urine than is provided in this protocol. Either might have accounted for the symptoms.

An attractive possibility is periarteritis nodosa, which can, of course, produce nephritis with albuminuria and hypertension, and which would explain some of the other findings that are difficult to account for, such as the skeletal symptoms that she experienced from time to time. These were vague, and I do not know how to interpret them, but vague skeletal symptoms are said to be a feature of periarteritis nodosa. I might say parenthetically that there are two types of periarteritis nodosa: one occurs incidentally along with other conditions, such as hypersensitivity, and the second causes the clinical syndrome of periarteritis nodosa. The latter, which I am incriminating here, is characterized by an insidious onset, with debility, weight loss and symptoms referable to the vascular system. There are vague skeletal pains, as I have said, and also lesions that are compatible with the description of those over the wrists and ankles in this patient. I am afraid, however, that there is not enough evidence here to make a diagnosis of periarteritis nodosa. In the first place, one expects to find eosinophilia, and there was not even a single eosinophil in the blood smear. In the second place, I rather suspect that, if she had died of periarteritis nodosa, she would have had a good many more symptoms referable to the vascular system, such as abdominal pain, pain in the extremities similar to intermittent claudication, cerebral phenomena and so forth. She had none of these, and it is im-

probable that she had periarteritis nodosa. I say that particularly because every time I discuss one of these cases I make that diagnosis and it is always wrong.

Before I go farther with the discussion I should like to see the x-ray films.

DR MILFORD D. SCHULZ: The films show what is stated in the protocol.

DR BECKMAN: Undoubtedly, but I do not understand what the protocol said.

DR SCHULZ: The films show fibrous lesions involving the apices. There seems to be something else going on, as shown by the areas of increased density extending from both hilar regions. Several rounded areas of increased density are seen in the lower portions of the lungs. One almost looks as if it had a fluid level.

DR BECKMAN: Could she have had pulmonary infarction?

DR SCHULZ: I wonder if she could have had multiple septic pulmonary emboli in addition to the old disease. The hilar vessels are rather prominent, but there does not seem to be pleural effusion. The heart is enlarged, and there is some prominence in the left auricular area. Calcification in the valves is not apparent.

DR BECKMAN: I still do not know what this patient had. She seems to have had an old pulmonary tuberculosis. I suppose that whether or not this was active cannot be told from the chest films, and in the absence of a sputum examination I cannot decide whether she had an active pulmonary tuberculosis. If it were active, it would account for the low-grade fever that she was running.

If one were to attempt to relate the whole picture,—the pulmonary and the renal disease,—I should think that one would have to bring in the possibility of chronic pulmonary sepsis—tuberculosis or some other disease—leading to amyloidosis, including amyloid kidneys, and thereby causing the train of events that took place. I do not have any way of establishing that diagnosis either, but it is unlikely in view of the high blood pressure, which is not frequent in renal amyloidosis. As a matter of fact, I can mention a lot of things but cannot establish any of them. As I have said, the terminal episode might have been due to left ventricular failure. The abrupt onset of breathlessness is consistent with that. It is rare, however, to have a marked feeling of substernal oppression in that syndrome. Although these patients sometimes complain of precordial discomfort, what this patient experienced is more than usual, and I wonder whether she might have had a large pulmonary embolus two days before admission to the hospital, which was the final cause of her death. I do not believe that I can settle any of these questions.

It seems likeliest that this patient had nephritis, either chronic glomerulonephritis or chronic pyelonephritis. There is no way of differentiating these

two, but I will bet on glomerulonephritis, with resulting hypertension and hypertensive heart disease, left ventricular failure and pulmonary edema. She also had an old pulmonary tuberculosis, which was probably inactive.

A PHYSICIAN Is carcinoma of the lung of common occurrence in women and is it ever bilateral?

DR BENJAMIN CASTLEMAN Primary carcinoma of the lung is more frequent in men than in women, but it certainly does occur in the latter. It is almost always unilateral. When it is bilateral, the lesions on one side are usually metastases from the other side.

Dr Schulz, do these films suggest carcinoma?

DR SCHULZ I do not know how one could rule it out, but it does not have to be primary in the lung.

DR E D MASON I have never seen anything like the rash on the ankles and wrists. It resembled post-mortem lividity, and we could not explain it. It was hemorrhagic and deep purplish.

DR REED HARWOOD If this patient had left ventricular failure, is it not surprising that she did not have more x-ray evidence of pulmonary congestion?

A PHYSICIAN A large liver is usually associated with right ventricular failure, rather than with left ventricular failure. What explains the large liver?

DR BECKMAN I doubt that it was really enlarged. When the liver is described as large in such vague terms, it usually turns out not to be. Dr Castleman will settle this point later.

CLINICAL DIAGNOSIS

Pulmonary tuberculosis, active

DR BECKMAN'S DIAGNOSES

Chronic glomerulonephritis

Hypertensive heart disease, with left ventricular failure

Pulmonary edema

Pulmonary tuberculosis, probably inactive

ANATOMICAL DIAGNOSES

Subacute glomerulonephritis

Hemorrhagic pulmonary edema, severe

Bronchopneumonia

Cardiac hypertrophy, hypertensive type, slight

Periarteritis nodosa, focal bronchial lymph node and pancreas

Pulmonary tuberculosis, healed, apical

PATHOLOGICAL DISCUSSION

DR CASTLEMAN Autopsy showed a pair of lungs that were quite heavy, being two or three times the normal weight. There were no adhesions or fluid in either pleural cavity. On section we were unable to find any cavities. In the right lung there was an old tuberculous scar surrounded by compensatory emphysema. It is quite possible that this focal emphysema might have produced an x-ray picture simulating a cavity. This scar was the only evidence of tuberculosis that we could find. The rest of the lungs were boggy and soggy, being full of fluid and blood. Every alveolus was filled with either blood or fluid, and some of them contained polymorphonuclear cells. In other words, this was an extremely severe form of hemorrhagic edema, the type that is often seen in patients with renal disease and the type that was recognized roentgenologically a few years ago by Dr Richard Schatzki,* of our x-ray department.

We did find renal disease. Each kidney weighed about 100 gm, and although the surfaces were smooth, they were studded with petechial hemorrhages. In gross the prosector, Dr J P Kujala thought that there probably was a nephritis. Microscopically it proved to be subacute glomerulonephritis. It apparently had gone on to the chronic stage, because none of the glomeruli were completely hyalinized and there was no surface granularity. That fits in with the size of the heart, which weighed only 250 gm, although the left wall was slightly hypertrophied.

An interesting incidental finding, which will probably please Dr Beckman, was the presence of periarteritis in two vessels, one in a hilar lymph node and the other in the pancreas. The kidneys, however, showed no evidence of periarteritis nodosa. I have not been able to find out whether the patient had ever been given sulfonamides, the thought being that it might have been the result of an allergic reaction.

DR BECKMAN How large was the liver?

DR CASTLEMAN It was within normal limits, weighing 1500 gm.

A M A PROGRAM

On page 224 is reprinted the platform that was adopted by the Council on Medical Education and Public Relations and the Board of Trustees of the American Medical Association on June 22 and that originally appeared in the July 21 issue of the *Journal of the American Medical Association*

Undoubtedly this program will do much to clarify the stand of the American Medical Association, and certainly the fulfillment of its principles would accomplish a great deal toward the improvement of medical care. On the other hand, it seems unfortunate that nothing is said regarding the promotion of co-operation and an improved understanding among groups and individuals concerned with the

provision of all types of medical care, that the political control or domination of medical practice is not denounced (rather than a plea being made for the "postponement of consideration of revolutionary changes"), that the need for additional and improved hospital facilities, particularly in rural areas, is ignored, that the necessity of providing adequate means for the postgraduate instruction of discharged medical officers and civilian physicians is disregarded, that the opportunities for advancement in the field of industrial medicine are not mentioned and, finally, that the possibilities connected with education of the public in matters pertaining to medicine, other than those concerned with voluntary insurance, are ignored. Anyone who is at all familiar with the activities of the American Medical Association appreciates that all these matters are receiving due attention, and why they were omitted from a statement purporting to present the ideas of the American Medical Association regarding ways and means for improving the health of the Nation is incomprehensible.

It is obvious that the American Medical Association can do little toward attaining the objectives of this platform. In other words, the program is a direct challenge to physicians and to the state agencies — medical societies, hospital associations, departments of health and so forth — that are involved in the provision of medical and hospital care. Much has to be done, and promptly, if Congress is to be convinced that the provisions contained in the Wagner-Murray Bill (S 1050) are ill advised and unnecessary.

"WHERE THERE IS NO VISION"

AFTER the war is over, according to the fixed beliefs of many people, — beliefs built firmly around their faith in the fulfillment of a personal wish, — many things will come to pass. Permanent peace will brood over the land, certainly so if our global friends and neighbors adopt our views on international matters, we shall return to the goodness of former days, separated in some mysterious manner from their evil, we shall have new radios, with television, wireless telephones so that we can

CONSTRUCTIVE PROGRAM FOR MEDICAL CARE

AMERICAN MEDICAL ASSOCIATION

This platform was adopted by the Council on Medical Service and Public Relations and the Board of Trustees of the American Medical Association on June 22, 1945

Preamble

The physicians of the United States are interested in extending to all people in all communities the best possible medical care. The Constitution of the United States, the Bill of Rights and the "American Way of Life" are diametrically opposed to regimentation or any form of totalitarianism. According to available evidence in surveys, most of the American people are not interested in testing in the United States experiments in medical care which have already failed in regimented countries.

The physicians of the United States, through the American Medical Association, have stressed repeatedly the necessity for extending to all corners of this great country the availability of aids for diagnosis and treatment, so that dependency will be minimized and independence will be stimulated. American private enterprise has won and is winning the greatest war in the world's history. Private enterprise and initiative manifested through research may conquer cancer, arthritis and other as yet unconquered scourges of humankind. Science, as history well demonstrates, prospers best when free and unshackled.

Program

The physicians represented by the American Medical Association propose the following constructive program for the extension of improved health and medical care to all the people:

- 1 Sustained production leading to better living conditions with improved housing, nutrition and sanitation which are fundamental to good health, we support progressive action toward achieving these objectives.
- 2 An extended program of disease prevention with the development or extension of organizations for public health service so that every part of our country will have such service, as rapidly as adequate personnel can be trained.
- 3 Increased hospitalization insurance on a voluntary basis.
- 4 The development in or extension to all localities of voluntary sickness insurance plans and provision for the extension of these plans to the needy under the principles already established by the American Medical Association.
- 5 The provision of hospitalization and medical care to the indigent by local authorities under voluntary hospital and sickness insurance plans.
- 6 A survey of each state by qualified individuals and agencies to establish the need for additional medical care.
- 7 Federal aid to states where definite need is demonstrated, to be administered by the proper local agencies of the states involved with the help and advice of the medical profession.
- 8 Extension of information on these plans to all the people with recognition that such voluntary programs need not involve increased taxation.
- 9 A continuous survey of all voluntary plans for hospitalization and illness to determine their adequacy in meeting needs and maintaining continuous improvement in quality of medical service.
- 10 Discharge of physicians from the armed services as rapidly as is consistent with the war effort in order to facilitate redistribution and relocation of physicians in areas needing physicians.
- 11 Increased availability of medical education to young men and women to provide a greater number of physicians for rural areas.
- 12 Postponement of consideration of revolutionary changes while 60,000 medical men are in the service voluntarily and while 12,000,000 men and women are in uniform to preserve the American democratic system of government.
- 13 Adoption of federal legislation to provide for adjustments in draft regulation which will permit students to prepare for and continue the study of medicine.
- 14 Study of postwar medical personnel requirements with special reference to the needs of the veterans' hospitals, the regular army, navy and United States Public Health Service.

be in constant touch with our offices while fishing, juicy steaks synthesized entirely from yeast and broiled over synthetic hickory coals, sun-warmed and air-conditioned plastic houses with electric blankets on every bed, and automobiles, swift as the wind, silent as a tropical night, low hung and streamlined to raindrop perfection, with scratch-proof finish and puncture-proof tires. (The last specification is particularly desirable since the wheels will be practically unapproachable.) These things are being virtually promised to us by the wizards of industry as our reward for toppling the statue of fascism from its pedestal and preparing the latter for the advent of a shapely goddess, holding in one hand a miniature Diesel engine and in the other a pair of run-proof nylon stockings.

We are issued a timely warning, however, by Arthur W. Stevens, president of the Automobile Safety Association, in a letter published by the *Boston Herald* on May 24. The contents of this letter should be of special interest to the physicians of the Nation, concerned as they are more in public health than in the not inconsiderable fees to be derived from the patching up of injuries resulting from automobile accidents. The majority of these accidents, according to Mr. Stevens's plausible premise, are invited by the design of the present passenger car, which places the driver halfway back toward the rear of the car, "shutting off his effective view of the road and its hazards with an exaggerated hood, wide-flung fenders and thick corner posts." If we continue with the same trends in design, he adds, our highway massacre of the past will be resumed and will achieve even more appalling heights.

Mr. Stevens, in concluding his letter, quotes from an authority who had acquired a reputation for wisdom a thousand years before our Christian era began, — King Solomon, — who once declared, "Where there is no vision the people perish." We trust that the automobile designers of the postwar period will take note of Solomon's words and apply them in a practical manner to their own peculiarly important profession. We have had enough of violent death. If cars cannot be both graceful and safe, then the designers should at least try to approach the latter goal.

We should like to make still another suggestion while in the mood. It should not be too difficult to meter automobile horns to a certain small number of sound seconds per month, when the allotted time for hornblowing has run out, the car is put off the road until a new period begins. It's worth dreaming about.

MASSACHUSETTS MEDICAL SOCIETY

DEATHS

BRESNIHAN — Frank N. Bresnihan, M.D., of Cambridge, died July 29. He was in his fifty-ninth year.

Dr. Bresnihan received his degree from Tufts College Medical School in 1913. He was a fellow of the American Medical Association.

His brother survives.

JACOBSON — Nathan L. Jacobson, M.D., of Lynn, died July 13. He was in his sixty-first year.

Dr. Jacobson received his degree from Maryland Medical College, Baltimore, in 1910. He was on the staffs of the Lynn and Union hospitals. He was a member of the Lynn Medical Association and the North Shore Medical Fraternity.

His widow, a son and a stepson survive.

RICHARDSON — Carl E. Richardson, M.D., of Franklin, died July 30. He was in his sixty-second year.

Dr. Richardson received his degree from Tufts College Medical School in 1907. He had been medical examiner of Norfolk County for twenty-one years. He was a fellow of the American Medical Association.

His widow, a son and a sister survive.

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

POSTPONEMENT OF ELECTIVE TONSILLECTOMY

Inquiries are now being received by the Department of Public Health concerning the advisability of doing elective tonsillectomies during the summer months.

The present incidence of poliomyelitis is somewhat higher than that for the corresponding period of last year. Although this does not constitute the threat of a serious outbreak, the department is of the opinion that elective tonsillectomies should be postponed until the poliomyelitis season is over.

MISCELLANY

CHANGES IN ISOLATION AND QUARANTINE PROCEDURES FOR SCARLET FEVER

In line with modern thought on this common disease of childhood the Board of Health [City of New York] radically revised its isolation and quarantine procedures in scarlet fever on December 12, 1944. The regulations now include

CONSTRUCTIVE PROGRAM FOR MEDICAL CARE

AMERICAN MEDICAL ASSOCIATION

- 14 Study of postwar medical personnel requirements with special reference to the needs of the veterans' hospitals, the regular army, navy and United States Public Health Service.

story. We may hope that Dr. Champion's paper will prompt many readers to look for themselves to those earlier records reposing for years in the recesses of our libraries, too easily overlooked by "modern" medicine and "modern" public health. The fuller meanings of the closely linked sympathy of those two outstanding characters of our past century unfold gradually to the thoughtful reader after the manner of the theme of Osler's "The Growth of Truth."

One part of the Shattuck-Bowditch story, evidently important in the time when our first state health authority was taking form, stems from Shattuck's enthusiastic conviction that necessary agents of the "sanitary reform" he envisioned and advocated so zealously must be physicians of such knowledge and character, as were still rare attributes of the profession of his time. As part of the argument of his report to the legislature in 1850 for more adequate public measures in the prevention of disease witness this statement concerning duties of medical officers of health in Appendix XI of the 1850 Commission Report. "Preventive medicine while it constitutes a special [science] is in itself the highest and most useful branch of medicine and requires in its missionaries a correspondingly long and special study to become useful promulgators of its doctrines and workers in its cause." On one of the very early pages of this same report, witness also his reference to the famous question, "Who is the physician who is an honor to his profession?" And the immortal answer, in words attributed to Hippocrates himself: "He who has merited the esteem and confidence of the public by profound knowledge, long experience and consummate integrity, who has been led through all the circle of the sciences

The complement to Mr. Shattuck's high ideals of the unrealized social potentials of the medical profession is Dr. Bowditch's high esteem of Mr. Shattuck personally, of the public ideals that Shattuck represented and of his part in the getting the idea of preventive medicine officially recognized and accepted in the Commonwealth. Glimpses of this part of the picture appear in several accessible records. *The History of the Massachusetts Medical Society*, by Dr. W. L. Burrage, tells much and implies more. Dr. Bowditch himself commemorating the first century of medicine in the United States in an address before the National Medical Congress in Philadelphia in 1876, referred to Shattuck as one of two outstanding characters of the English-speaking world "prominent in their relation to the third epoch or that in which the medical profession is aided by the laity." In speaking further of Shattuck he said "There is no doubt that he, as a layman quietly working did more toward bringing Massachusetts to correct views on this subject than all other agencies whatsoever."

Pioneers of Public Health by M. E. M. Walker, contains a chapter on Shattuck along with those on Jenner, Pasteur, Lister and other such notables. This same manual refers also to that portion of Dr. Bowditch's centennial address of 1876 which reads as follows:

Twenty-five years ago viz. in 1850 a report of the Sanitary Commission of Massachusetts was printed by order of the Legislature. It was written chiefly, if not entirely, by a layman—Lemuel Shattuck, Esquire, an earnest sanitarian of that day. As I read it now after a lapse of a quarter of a century since it was written and presented to the Legislature I wonder at the wisdom of its suggestions and learn much from them. I remember Mr. Shattuck well—calm in his perfect confidence in the future of preventive medicine to check disease, he walked almost alone the streets of his native [adopted] city—not only unsustained by the profession but considered by most of them an offense of his candid advocacy of what seemed to the majority of physicians to be out of the layman's sphere and withal of trifling moment compared with our usual routine of so-called practice.

Thus in 1876, Dr. Bowditch one-time secretary of the Massachusetts Medical Society and one-time secretary of the American Medical Association chosen to review for assembled physicians of all nations the first century of medicine in the United States declared concerning the "third epoch" or that in which the medical profession had been aided by the laity, "The ruling idea of this epoch is still in its infancy but shows by what it has already accomplished trivial though this performance may seem at first glance to be its inherent

and great power, its objects are vastly wider than those of any preceding epoch." In that courageous declaration of young American medicine there appeared a vigorous new witness to the ancient truth that from time to time in the affairs of men, traditional antitheses unite in a new birth of freedom in procreative thought and action.

In the first annual report (1870) of the State Board of Health "to the honorable Senate and House of Representatives," Dr. Bowditch, as secretary, defined "the essential principles of action" of the new board and the place of physicians in carrying out those principles of action in these words:

By the careful and comprehensive study of these various laws [of health and life] and their relations the highest department of the physician's art is brought into operation, but no man or private body of men has the ability to study and develop this department as a free commonwealth can do when acting through the agency of a few persons who are devoted to this object and who come willingly to the work and armed with the power and ample means of the state.

In terms of individual life, seventy-five years means venerable maturity. In terms of growth of a social discipline, it usually means something quite different. The "ruling idea" of that epoch in which the medical profession was aided by the laity was only in its infancy when it imparted its drive to the developments that have become "seventy-five years of public health in Massachusetts" and that have lent their sanction to and determined the pattern of most of our subsequent public-health legislation.

What can this seventy-fifth anniversary report tell of the present "physical stature" and "mental age" of that promising infant idea, which Dr. Bowditch spoke of as the "ruling idea" of the new epoch? Today that same idea has rich possibilities that Shattuck and Bowditch could hardly have imagined. Compared with their time, this is a time of vastly amplified power and means, "professional" and "lay," within the society that is our commonwealth operating under the liberal principles of our social philosophy and of our chosen form of government. The stirring environment of this larger world, which sets new premiums on physical power and moral and spiritual stamina, also begins to define new objectives to give direction to this amplified power and means. Furthermore, against the background of the Shattuck-Bowditch time, we are a profession generously qualified to exercise our responsibilities in an enlarged "practice" in sincere fearless forward moving collaboration with the peoples who are today's "laity" through their agencies of government and other agencies of organized power and action.

The names of Pasteur and Lister have long stood for an epoch of the advance of medicine as a biologic science and art. Is it a too daring draft on our account with destiny to expect an equally distinguished maturity for the vigorous Shattuck-Bowditch conception of medicine as a social science and a growing social practice carrying the full benefits of medical knowledge to every family and every person in the Commonwealth? Of that idea which he considered then "the ruling idea—still in its infancy," Dr. Bowditch said in 1876 "Its early manhood will not be reached until far toward the termination of the next century."

Again we thank Merrill Champion for his timely contribution to the "child hygiene" of Massachusetts medicine.

HAROLD W. STEVENS, M.D.

56 Front Street
Marion, Massachusetts

MIDDLESEX MEDICAL SOCIETY

To the Editor: In "The History of Middlesex North District Medical Society," which appeared in the July 12 issue of the *Journal*, Dr. Gardner states that the first medical association in Middlesex County was formed in 1829. Thacher's *American Medical Biography*, in its account of the Honorable Oliver Prescott, M.D., M.M.S. and A.A.S., states on page 429 of Volume I that he was "president of the Middlesex Medical Society during the whole period of its existence." Dr. Prescott was born in Groton in 1731 and died (of a pectoral dropsy) in 1804. What his "Middlesex Medical Society" amounted to

scarlet fever in the larger classification of "streptococcal sore throat, including scarlet fever," and change the isolation period in cases with no septic complications to the duration of the acute stage, the minimum period being seven days. The Board of Health further eliminated quarantine of household contacts to scarlet fever, making it no longer a requirement that such contacts stay out of school or work.

The action of the Board of Health was based on several factors. The first and most important of these is the fact that scarlet fever should not be considered a disease entity in itself, independent of other streptococcal throat infections. A large body of scientific work—clinical, bacteriological, immunological and epidemiological—indicates that the same hemolytic streptococcus (group A streptococci) which causes in one person septic sore throat, in another erysipelas and in a third puerperal sepsis may cause in a fourth the syndrome which for centuries has been known as scarlet fever. The type of clinical disease produced by infection depends on a number of factors—such as the previous history of streptococcal infection, the portal of entry of the infection and, to a certain extent, the characteristics of the particular strain of organism.

In many cases, the only distinction between septic sore throat and scarlet fever is the appearance of the rash, and there is ample evidence to indicate that the absence or presence of the rash is a phenomenon dependent on the individual's ability to withstand the so-called erythrogenic toxin of the hemolytic streptococcus. In other words, given two susceptible individuals exposed to the same hemolytic streptococcus, one person, because he is immune to the rash-producing mechanism, will have a sore throat without a rash, while the other person, nonimmune to this rash-producing toxin, will have scarlet fever. To have different regulations for persons suffering from the same disease, either with or without a rash, has for a considerable length of time been considered inconsistent.

The ineffectiveness of former quarantine measures was a second reason for the Board's decision. The age-old isolation measures, drastic as they were, had little or no effect on the incidence of streptococcal disease in general throughout the city. Moreover, from 1900 to the present there were different periods of isolation, yet there does not seem to be any close correlation between strict or liberal control of cases and the incidence of the disease. It seemed wiser, therefore, to put all streptococcal throat infections into one category with the same restrictive measures applying to all of them.

The majority of streptococcal throat infections, including scarlet fever, run their course in a week, and the hemolytic streptococcus responsible for the disease disappears in many cases or is reduced in numbers very considerably as soon as clinical recovery occurs. Since there are probably many more carriers of the hemolytic streptococci responsible for streptococcal throat infections including scarlet fever in the general population than in recovered cases, it was an undue hardship to require the strict isolation of convalescent streptococcal sore throat patients and scarlet fever convalescents until they were bacteriologically noninfectious, while allowing other carriers complete freedom of action.

The statement is occasionally made that complications of scarlet fever often do not set in until the second week, and that, consequently, cases should be isolated for at least two weeks. It is to be noted, therefore, that according to the Sanitary Code, cases of scarlet fever are isolated until recovery, but for a period of not less than one week. Complications following sore throat without a rash also frequently occur in the second week. Formerly such cases were not isolated.

A third reason for modifying the restrictions on scarlet fever was the experience which New York City shared with most of the United States and, in fact, with a great part of the world. Scarlet fever has become increasingly benign. It apparently reached a peak of severity during the last half of the nineteenth century and, since about 1875, has steadily become less severe. Available morbidity and mortality rates show a decrease in the case fatality rate of approximately 95 per cent from the earliest recorded rates to those of the present. This decline, however, has not been uniform, the northern states and urban areas showing more marked decreases than the southern states and rural areas. There seems to be no obvious explanation of this trend, but in the United States at the present time, there is no doubt that we are in a very mild phase of the cycle of the disease.

deaths from scarlet fever in New York City are becoming very infrequent and the disease itself from the clinical standpoint certainly is a much milder one than is ordinarily associated with the word scarlet fever.

It was only after very careful consideration of the entire situation that the Board of Health, in line with the scientific evidence adduced above, modified the New York City regulations regarding scarlet fever. The New York State Department of Health, through its Public Health Council, adopted similar regulations.—Reprinted from *Quarterly Bulletin, Department of Health, City of New York, July, 1945*

* * *

The above article explains, in more or less detail, the reasons for changes recently made by the New York City Department of Health regarding the isolation of patients with scarlet fever. These regulations were commented on editorially in the May 10 issue of the *Journal*.—Ed

CORRESPONDENCE

THE SUFFIX "-OSIS"

To the Editor Having been educated at the feet of those Harvard scholars who challenge the world with their pronunciation of such words as "vertebral," "trachea" and "appendicitis," I have also developed somewhere along the line an acquired (or—shades of my Salem ancestors—could it be an atopic?) sensitivity to words ending in "-osis." Consequently I read with particular interest both the title and the substance of the article "Death from Sulfadiazine with Agranulocytosis, Jaundice and Hepatosis" by Ziegler et al. in the July 19 issue of the *Journal*.

Perhaps my Gould's dictionary is obsolete, but it does not give a definition of hepatosis. It does list "nephrosis (any renal disease)" and "polypsis (the condition of being afflicted with polyps)." What I should like to know is, is a person with hepatosis afflicted with livers or does he just have any old hepatic disease?

GEOFFREY EDSALL, MD

36 Follen Street
Cambridge 38, Massachusetts

* * *

The *Journal* has often been criticized for its use of "-ic" and "-ical," but this is the first time that "-osis" has been so honored. According to Dorland's *American Illustrated Medical Dictionary* (twentieth edition), nephrosis means "any functional disorder of the liver." Since autopsy in the case referred to by Dr. Edsall failed to show a definite pathologic lesion, the word in question appears to be the proper one to have used.—Ed

SHATTUCK AND BOWDITCH

To the Editor The leading article in the March 1, 1945 issue of the *Journal*, "Seventy-Five Years of Public Health in Massachusetts," is a timely reminder of one of those momentous conjunctions of individualities which, from time to time, have lighted new beacons and reset the course of progress.

Somewhat earlier, the names of Edwin Chadwick and Dr. John Simon had become associated in the English language of public health. About the same time, the names of Pasteur and Lister were coming to stand for new ideas in the science and the practice of surgery and medicine.

We all may be grateful to Merrill Champion for his terse restatement of long-recorded facts which made the Shattuck-Bowditch phenomenon of our own commonwealth one of those luminous combinations of personalities and ideas that is still a herald of light to illumine the present status of Massachusetts medicine and to project at least one ray beyond our present day.

Dr. Champion's account of Lemuel Shattuck as "pioneer" and Dr. Henry I. Bowditch as "organizer" is a well balanced sketch of outstanding events of the period 1849 to 1879, in which have proved so full of meaning for public health in the Commonwealth and beyond our boundaries. Naturally, the pages of such an article cannot reproduce the complete

LIGATION OF THE INFERIOR VENA CAVA FOR THE PREVENTION OF PULMONARY EMBOLISM*

A Report of Two Cases

EUGENE A. GASTON, M.D.,† AND HUGH FOLSOM, M.D.‡

FRAMINGHAM, MASSACHUSETTS

THROMBOSIS in the deep veins of the lower extremities has been shown to be a frequent source of postoperative pulmonary emboli. The demonstration by Homans,¹⁻³ Frykholm⁴ and others that such thromboses usually begin in the veins of the foot or lower leg, with later extension into the femoral and iliac veins, has led to enthusiastic attempts to prevent embolic sequelae by venous ligation proximal to the thrombotic process. Because of their easy accessibility and the fact that in early cases they lie above the site of thrombosis, the superficial and common femoral veins have generally been chosen as the sites of ligation.

The results of femoral-vein ligation have been encouraging not only for the prevention of pulmonary embolism but as a means of preventing the chronic, disabling symptoms that otherwise result. In a small percentage of cases, from the development of a full-fledged phlegmasia alba dolens. In 1941, Sears⁵ reported 10 cases of femoral-vein ligation with no untoward results. In 1943, Allen, Linton and Donaldson⁶ reported ligations in 202 patients, in 78 cases bilateral ligation was done. The postoperative sequelae in this series were surprisingly few, edema of the legs being the most serious. The average patient wore an elastic bandage for a period of only three or four weeks before regarding it as unnecessary. It was also found that early swelling of the legs was slightly more frequent following interruption of the common femoral vein, whereas late edema was about equally frequent following ligation of the superficial or common vein.

Homans⁷ has recently suggested that when a partially obstructing thrombus is found at or above the level of the common femoral vein, ligation of the common iliac vein gives greater protection against

embolism than does removal of the thrombus and ligation of the common femoral vein. He points out that ligation of the common iliac vein also allows a more satisfactory collateral pathway for venous return around the point of ligation. This collateral pathway extends upward through the deep circumflex iliac and deep epigastric veins. Of more importance are the internal iliac (hypogastric) veins, whose numerous anastomoses with each other allow the blood to be shunted across the pelvis to the iliac vessels of the side opposite the ligation. In a series of 14 common iliac interruptions no postoperative edema was noted.

The advantages of common iliac vein ligation are to a certain extent outweighed by the more extensive operative procedure that is required to isolate this vessel. Homans has used an extraperitoneal approach that is satisfactory only for unilateral ligation. He states that ligation of the inferior vena cava is probably indicated in the presence of bilateral thrombosis and is certainly to be preferred to bilateral common iliac vein ligation. The experience of Allen, Linton and Donaldson⁶ in regard to bilateral thrombosis is of interest in this connection. They state, "We have found thrombosis in so many supposedly normal extremities that we are inclined to feel that simultaneous routine interruption of the opposite [femoral] vein should be undertaken." If it is true that venous thrombosis is a disease that frequently affects the vessels of both lower extremities and if, in advanced cases of femoroiliac thrombosis, it is true, as it almost certainly is, that ligation above the site of thrombus formation gives added protection against embolism, ligation of the inferior vena cava seems desirable, first to interrupt the venous channel above the evident femoroiliac thrombosis, and second to prevent embolism from a simultaneous, subclinical phlebothrombosis that is probably frequently present in the veins of the opposite lower leg.

Although it seems evident that, in the great ma-

MEDICAL SCHOOLS AND COMPULSORY MEDICAL INSURANCE

To the Editor This is a note on a possible solution of the question as to the position of medical schools under compulsory medical insurance

This year the Governor of California introduced a compulsory health insurance bill (A B 800). The Congress of Industrial Organizations, which had long been studying health insurance, introduced another bill (A B 449) that differed from the Governor's on several important details

The Governor's bill made no reference to medical schools. After the Governor, however, had consulted with the deans of the four schools in the State he announced that if the schools should happen to treat beneficiaries under the act they would not ask that more than their expenses be covered and that so far as teaching was concerned "medical indigents" would still be available

Under the CIO bill, indigents received benefits and the number of those covered by the provisions of service was so large that the point was raised that most of the people who are now coming to the medical schools might go to private doctors. The authors of the CIO bill recognized the seriousness of this possibility in regard to medical teaching. They looked on medical schools as the organizations best equipped to forward that maintenance and improvement of the quality of medical care without which a mere extension in quantity might prove a dubious blessing. Therefore, the bill provided that representatives of medical schools be appointed on both the central and local governing bodies under the act. To make sure that these representatives should be in close touch with advancing knowledge it was required that they should be selected from those who were in whole-time investigation and teaching. To avoid the danger of bureaucratic or political interference it was provided that medical schools, or any other group capable of giving complete and adequate medical service, might be paid a lump sum for all they did, leaving them free to spend the money in any way they desired. Universities might thus give some of it to research work and some of it to younger men who now work for nothing. The indications were that the amount of money that would be thus put at the disposal of the universities might be so large that the present crippling of medical-school work from lack of money would largely disappear. With practice passing more and more into the hands of a series of interconnected groups of doctors, working in rural areas around medical centers, in district towns around hospitals and coming to an apex in medical schools, it was felt that people would be eager to be treated by medical-school groups and that the great majority would welcome a discussion of their medical problems with medical students

The reaction of medical students to these proposals in the CIO bill was interesting. At the University of California Medical School, 106 students signed a petition to their dean in which the advantages of the plan for all medical schools were stressed. At Stanford, 209 students, practically the entire student body who could be reached in the time available, sent a petition to the Dean, the President, the Board of Trustees and the Alumni Association urging them to work for the adoption of the medical-school provisions of the bill. This substantial unanimity was achieved because the question of the advisability of compulsory medical insurance was not raised. The point that they were making was that if compulsory insurance became law they wanted their medical schools to take an active part in maintaining and advancing the quality of the care given to the people, to accept from the government the money due to the schools for the services they rendered and to maintain their freedom by keeping the disposal of the money received in the hands of the universities

Although this bill was killed in committee, the question of the status of medical schools under compulsory medical in-

surance will be raised again, and so the plan that was proposed is still important as the first constructive solution of a difficult problem that has found expression in concrete legislative form

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request

The Woman Asks the Doctor By Emil Novak, M.D., associate in gynecology, Johns Hopkins University School of Medicine, and gynecologist, Bon Secours and St. Agnes hospitals. 8°, cloth, 130 pp., with 11 illustrations. Second edition. Baltimore: Williams and Wilkins Company, 1944. \$1.50

Much new material has been added to this second edition of a popular work on menstruation and its disorders. The author, who is an eminent gynecologist, discusses only those problems in which all women are interested and those in which he believes they most need instruction. This manual is recommended for collections on popular medicine.

ated with gauze strips saturated with boric acid ointment and held in place with firm elastic bandages. On this regimen evidence of sepsis disappeared and rapid epithelialization on both the periphery and numerous small epithelial "islands" occurred. On the 22nd day, the patient was allowed out of bed, and during the next 4 days she was permitted progressively increasing activity.

On the 27th day, the patient first complained of pain in the right chest posteriorly. This pain was associated with a rise in temperature to 102°F and sudden elevation of the respiratory rate to 38. Auscultation of the chest showed no evidence of consolidation, but coarse, moist rales were heard at the base of the right lung posteriorly. An x-ray film of the chest showed a small area of increased density. The legs were carefully examined. The burned areas were free of sepsis and completely epithelialized except for a few small areas, approximately 1 cm in diameter, which were covered with healthy granulation tissue. There was no evidence of deep superficial phlebitis in either leg. The dorsalis pedis and posterior tibial arteries showed good pulsation. The legs were warm, with no evidence of peripheral vasoconstriction, there was no dilatation of the veins or evidence of edema. Homans's sign was negative, and no tenderness was elicited over the femoral veins or the calves.

In the belief that the patient had an asymptomatic phlebotrombosis, probably arising in the veins of the lower extremities, operation was immediately performed under local anesthesia. Because the burned areas extended over the lower thirds of the thighs, areas drained by the deep femoral veins, the common femoral vein on each leg was isolated, doubly ligated and divided. Before ligation each vein was opened between traction ligatures. No evidence of clot was found, and there was a free flow of blood from both the proximal and distal segments.

Following bifemoral ligation the chest pain promptly disappeared and, within the first 24 hours, the pulse and respiratory rates fell to normal. Bicycle exercises were started immediately after operation, and on the 3rd postoperative day the patient was allowed out of bed. In spite of the improvement in her general condition, however, the temperature continued to fluctuate between 99 and 101°F. Three days after the femoral ligations the rales at the right base had disappeared. On this day the patient complained of slight pain over the lower chest anteriorly, which lasted only a few minutes and was not associated with an increase in respiratory rate. An x-ray film of the chest taken on the following day showed no change in the area of increased density previously noted at the base of the right lung.

Eight days after the bifemoral ligation the patient was awakened by the sudden onset of severe pain in the mid-clavicular region, associated with an elevation of the pulse and respiratory rate. A third x-ray film of the chest showed no change in the area at the right base, the left lung remaining clear. An electrocardiograph showed inversion of T₂ with slight right-axis deviation. The patient appeared acutely ill, there was slight cyanosis of the lips and fingernails, and her respirations were deep and labored. She was immediately placed in an oxygen tent, with some improvement in color. Intravenous fluids were administered, and 8 hours later her condition had improved sufficiently so that ligation of the inferior vena cava was undertaken, since it seemed evident that she had suffered a major pulmonary infarction.

Ligation of the inferior vena cava was done under spinal anesthesia through a long right paramedian incision in the center of which was at the level of the umbilicus. With the patient in the Trendelenburg position, the intestine was displaced into the upper abdomen and the posterior parietal peritoneum was incised to the right of the midline over the inferior vena cava. The cava was freed from the aorta without difficulty and doubly ligated with nylon ties, at the level of the bifurcation of the aorta. The duodenum and right ureter were identified and care was taken to avoid injury to them.

During the operation the blood pressure fell to 90/60, but responded promptly to the administration of intravenous glucose solution. At the end of the operation, which required 75 minutes, the blood pressure was 130/85. The pulse reached a maximum of 100 during the operation. When the patient was transferred to bed, however, it promptly rose to 150, but during the next 2 hours fell to 130, where it remained for the following 48 hours. The continued elevation of the pulse during this period was a matter of some concern, since it was

feared that, owing to the accumulating edema fluid in the legs, it might be an indication of incipient shock. The pulse, however, did not respond to the administration of intravenous fluids consisting of glucose in distilled water, whole blood and plasma. Because the respirations continued to be somewhat labored and slight cyanosis persisted, the patient was placed in an oxygen tent on the 2nd postoperative day. Shortly thereafter the pulse fell to 100. The rapid pulse was therefore believed to be due to diminished vital capacity resulting from the pulmonary infarct.

The circulation of the lower extremities was followed closely. Immediately following operation the skin of the feet, legs and thighs was mottled and cyanotic. This persisted for only a few hours. The arterial pulsations of both feet remained good. The legs were kept elevated on pillows and, at the end of 24 hours, only the slightest amount of pitting edema could be found around the ankles. This had increased slightly at the end of 48 hours. Thereafter both legs were securely bound with elastic bandages from the toes to the groins and further edema did not accumulate while the patient remained in bed.

During the first 2 postoperative days there was profuse sweating, and this, together with mild edema of the lower extremities, caused the urinary output to be low in spite of adequate amounts of intravenous fluids. At the end of this interval the blood nonprotein nitrogen had risen to 58 mg per 100 cc. The total serum protein was 8 gm per 100 cc. On the 3rd postoperative day the sweating became less and the urinary output increased, but the nonprotein nitrogen did not fall to normal until the 6th postoperative day.

After the first 48 hours the patient's general condition progressively improved. The wound healed by first intention. Bicycle exercises were started on the 3rd postoperative day and were continued several times daily thereafter. She was allowed out of bed on the 12th day, with the legs and thighs tightly swathed in elastic bandages. Only slight pitting edema of the lower thirds of the legs and of the ankles occurred when she became ambulatory. She was discharged from the hospital in good condition on the 18th postoperative day. Before discharge an effort was made to secure a phlebogram to demonstrate the collateral circulation around the ligated common femoral veins and around the caval ligation. These efforts were unsuccessful because the small size of the veins would not permit sufficiently rapid introduction of the dye. The small foot veins also made it impossible to secure satisfactory venous pressure readings.

Two months after the operation the patient's only complaint was of pitting edema of both lower legs. At that time enlarged veins extended from the groins upward along the lateral aspects of the abdomen and chest to the axillae. Four months after operation these veins had entirely disappeared, there was no evidence of peripheral edema, and the patient was allowed to return to light work.

CASE 2 A 71-year-old man was admitted on August 17, 1944, complaining of painful swelling of the left foot of 1 week's duration. Nine months previously he had noted a draining sinus on the medial aspect of the first metatarsophalangeal joint, which had persisted for 1 week. Thereafter he remained well until 1 week before admission, when pain, tenderness and local swelling recurred. Three days later a slight purulent discharge was noted. During the 4 days preceding admission the pain, swelling and tenderness became progressively worse and he was referred to the hospital by his physician.

Thirty-five years previously the patient was told that he had heart disease. His only symptom was mild dyspnea on exertion. Fifteen years later, cholecystectomy and appendectomy were done. Otherwise the past history was non-contributory.

Physical examination revealed a well developed and well nourished man who appeared to be acutely ill. The temperature was 101.6°F, the pulse 90, and the respirations 24. The head and neck showed no abnormalities. Excursions of the chest were equal but limited on both sides. The lung fields were resonant, with vesicular breathing throughout. Scattered, fine, moist rales were heard at the bases of both lungs. The heart was slightly enlarged, the left border of dullness being 2 cm outside the midclavicular line. A soft systolic murmur was heard at the apex. The blood pressure was 180/100. The abdomen showed a well healed scar over the right upper rectus muscle but was otherwise normal. The

majority of cases, pulmonary embolism arises from venous thromboses that originate in the veins of the lower leg and later progress upward to involve the pelvic veins, there are some cases in which the thrombotic process arises in the pelvic veins themselves. Rössle⁸ found from post-mortem studies that the hypogastric and iliac veins were involved in the thromboembolic process without involvement of the veins of the calf in only about 10 per cent of cases. Bauer,^{9, 10} however, concluded from venographic studies that almost invariably the thromboembolic process starts in the deep, large venous trunks of the lower leg.

Henderson,¹¹ reporting on 313 cases of fatal pulmonary embolism among surgical cases that came to autopsy, found the origin of the emboli in 189 cases to be as shown in Table 1. In some of the

cases two or even three sites of thrombosis were found. It is to be noted that in this series of 227 veins involved by thrombosis, 196 (86 per cent) were direct or indirect tributaries of the lower third of the inferior vena cava.

Numerous reports of experimental rapid occlusion of the inferior vena cava by ligation have been published, beginning with the work of Lower¹² in 1669. It has been repeatedly and conclusively shown that ligation above the level of the renal veins results in death, usually with an accompanying anuria and uremia. Below the level of the renal veins experimental ligation of the inferior vena cava is compatible with life, carries a low mortality rate and is associated with only slight and transient edema of the lower extremities.

Ligation of the inferior vena cava in man has been reported with increasing frequency. Pleasants¹³ in 1911, in a fairly complete review of the literature, found reports of 8 cases in which surgical ligation of the inferior cava had been performed. In all these cases ligation was done in connection with operations on the kidney. Ochsner and DeBakey¹⁴ in 1941 commented on a series of 48 cases of caval ligation, collected by Krotoski, chiefly performed for septic thrombophlebitis resulting from puerperal infection.

Collins, Jones and Nelson^{15, 16} in 1943 reported series of 41 cases of pelvic thrombophlebitis proved at operation or at autopsy. Pulmonary embolism was found in 85 per cent. In 8 cases ligation of the inferior vena cava was done, with 1 death, a mortality of 13 per cent.

From the above considerations it seems evident that ligation of the inferior vena cava below the level of the renal veins, although an operation of considerable magnitude, is compatible with survival in both experimental animals and man. A consideration of the available collateral pathways for venous return around the point of ligation^{7, 12} indicates that an eventual return to normal venous pressure relations should ensue. That this is true, as shown clinically by the gradual disappearance of post-operative edema, is evidenced by the end results of the cases presented below.

The indications for ligation of the inferior vena cava are not well defined. The following cases are presented to illustrate two situations in which such an operation has been followed by recovery. In each case the caval interruption probably forestalled a fatal issue by preventing massive pulmonary embolism. At the time of caval ligation both had suffered multiple pulmonary infarcts. From the standpoint of the peripheral venous system the indications for caval interruption were thrombosis arising in and confined to the veins of the pelvis, and iliac thrombosis arising by propagation from the vessels of the leg and associated with possible or probable thrombosis in the veins of the opposite leg.

CASE REPORTS

CASE 1. A 49-year-old, married woman was admitted to the Framingham Union Hospital on July 8, 1944, complaining of burns of the inner aspect of both thighs. The past history was significant in that 24 years previously, following the birth of the first child, the veins of the right lower leg became prominent and painful. The patient could recall no swelling of the leg, although her obstetrician told her that she had phlebitis. The post-partum course was otherwise normal. Since this episode occasional prominence of superficial veins below the right patella associated with a "drawing sensation" had been noted, although there had never been any edema of the leg or ankle.

Shortly before admission to the hospital, a pot of coffee was dropped and the patient received burns of the anteromedial aspects of both thighs just above the knees. Examination revealed a well developed, somewhat obese woman who appeared to be in good health. The general physical examination disclosed nothing of note. The heart and lungs were normal, and the blood pressure was 147/90. On the anteromedial aspect of both thighs, just above the knees, were areas of vesication from the burns, each 15 cm in diameter. No abnormalities of the peripheral circulation were noted in either of the lower extremities. Each of the burned areas was debrided and sprayed with 1 per cent aqueous gentian violet until a firm eschar had formed.

Laboratory examination showed the urine to be acid with a specific gravity of 1.025 and to contain 30 mg per 100 cc of albumin. There was no sugar. The sediment showed no cells but innumerable bacteria. The red-cell count was 4,850,000 and the hemoglobin 15.5 gm. The white-cell count was 6400, with a normal differential count.

Except for a low-grade fever caused by mild infection of the burned areas, and easily controlled by removal of the gentian eschar, the first 2 weeks of hospitalization were without incident. During the 3rd week the burned areas were

ted with gauze strips saturated with boric acid ointment held in place with firm elastic bandages. On this regimen evidence of sepsis disappeared and rapid epithelialization on both the periphery and numerous small epithelial "islands" occurred. On the 22nd day, the patient was allowed out of bed, and during the next 4 days she was permitted progressively increasing activity.

On the 27th day, the patient first complained of pain in the chest posteriorly. This pain was associated with a rise in temperature to 102°F and sudden elevation of the respiratory rate to 38. Auscultation of the chest showed no evidence of consolidation, but coarse, moist rales were heard at the base of the right lung posteriorly. An x-ray film of the chest showed a small area of increased density. The legs were carefully examined. The burned areas were free of sepsis and completely epithelialized except for a few small areas, approximately 1 cm in diameter, which were covered with healthy granulation tissue. There was no evidence of deep superficial phlebitis in either leg. The dorsalis pedis and anterior tibial arteries showed good pulsation. The legs were warm, with no evidence of peripheral vasoconstriction, there was no dilatation of the veins or evidence of edema. Homans' sign was negative, and no tenderness was elicited over the popliteal veins or the calves.

In the belief that the patient had an asymptomatic phlebotrombosis, probably arising in the veins of the lower extremities, operation was immediately performed under local anesthesia. Because the burned areas extended over the lower thirds of the thighs, areas drained by the deep femoral veins, a common femoral vein on each leg was isolated, doubly ligated and divided. Before ligation each vein was opened between traction ligatures. No evidence of clot was found, and there was a free flow of blood from both the proximal and distal segments.

Following bifemoral ligation the chest pain promptly disappeared and, within the first 24 hours, the pulse and respiratory rates fell to normal. Bicycle exercises were started immediately after operation, and on the 3rd postoperative day the patient was allowed out of bed. In spite of the improvement in her general condition, however, the temperature continued to fluctuate between 99 and 101°F. Three days after the femoral ligations the rales at the right base had disappeared. On this day the patient complained of slight pain over the lower chest anteriorly, which lasted only a few minutes and was not associated with an increase in respiratory rate. An x-ray film of the chest taken on the following day showed no change in the area of increased density previously noted at the base of the right lung.

Eight days after the bifemoral ligation the patient was awakened by the sudden onset of severe pain in the mid-apical region, associated with an elevation of the pulse and respiratory rate. A third x-ray film of the chest showed no change in the area at the right base, the left lung remaining clear. An electrocardiograph showed inversion of T₁ with slight right-axis deviation. The patient appeared acutely ill, there was slight cyanosis of the lips and fingernails, and the respirations were deep and labored. She was immediately placed in an oxygen tent, with some improvement in color. Intravenous fluids were administered, and 8 hours later her condition had improved sufficiently so that ligation of the inferior vena cava was undertaken, since it seemed evident that she had suffered a major pulmonary infarction.

Ligation of the inferior vena cava was done under spinal anesthesia through a long right paramedian incision, the center of which was at the level of the umbilicus. With the patient in the Trendelenburg position, the intestine was displaced into the upper abdomen and the posterior parietal peritoneum was incised to the right of the midline over the inferior vena cava. The cava was freed from the aorta without difficulty and doubly ligated with nylon ties, at the level of the bifurcation of the aorta. The duodenum and right ureter were identified and care was taken to avoid injury to them.

During the operation the blood pressure fell to 90/60, but responded promptly to the administration of intravenous glucose solution. At the end of the operation, which required 5 minutes, the blood pressure was 150/85. The pulse reached a maximum of 100 during the operation. When the patient was transferred to bed, however, it promptly rose to 150, but during the next 2 hours fell to 130, where it remained for the following 48 hours. The continued elevation of the pulse during this period was a matter of some concern, since it was

feared that, owing to the accumulating edema fluid in the legs, it might be an indication of incipient shock. The pulse, however, did not respond to the administration of intravenous fluids consisting of glucose in distilled water, whole blood and plasma. Because the respirations continued to be somewhat labored and slight cyanosis persisted, the patient was placed in an oxygen tent on the 2nd postoperative day. Shortly thereafter the pulse fell to 100. The rapid pulse was therefore believed to be due to diminished vital capacity resulting from the pulmonary infarct.

The circulation of the lower extremities was followed closely. Immediately following operation the skin of the feet, legs and thighs was mottled and cyanotic. This persisted for only a few hours. The arterial pulsations of both feet remained good. The legs were kept elevated on pillows and, at the end of 24 hours, only the slightest amount of pitting edema could be found around the ankles. This had increased slightly at the end of 48 hours. Thereafter both legs were securely bound with elastic bandages from the toes to the groins and further edema did not accumulate while the patient remained in bed.

During the first 2 postoperative days there was profuse sweating, and this, together with mild edema of the lower extremities, caused the urinary output to be low in spite of adequate amounts of intravenous fluids. At the end of this interval the blood nonprotein nitrogen had risen to 58 mg per 100 cc. The total serum protein was 8 gm per 100 cc. On the 3rd postoperative day the sweating became less and the urinary output increased, but the nonprotein nitrogen did not fall to normal until the 6th postoperative day.

After the first 48 hours the patient's general condition progressively improved. The wound healed by first intention. Bicycle exercises were started on the 3rd postoperative day and were continued several times daily thereafter. She was allowed out of bed on the 12th day, with the legs and thighs tightly swathed in elastic bandages. Only slight pitting edema of the lower thirds of the legs and of the ankles occurred when she became ambulatory. She was discharged from the hospital in good condition on the 18th postoperative day. Before discharge an effort was made to secure a phlebogram to demonstrate the collateral circulation around the ligated common femoral veins and around the caval ligation. These efforts were unsuccessful because the small size of the veins would not permit sufficiently rapid introduction of the dye. The small foot veins also made it impossible to secure satisfactory venous pressure readings.

Two months after the operation the patient's only complaint was of pitting edema of both lower legs. At that time enlarged veins extended from the groins upward along the lateral aspects of the abdomen and chest to the axillae. Four months after operation these veins had entirely disappeared, there was no evidence of peripheral edema, and the patient was allowed to return to light work.

CASE 2 A 71-year-old man was admitted on August 17, 1944, complaining of painful swelling of the left foot of 1 week's duration. Nine months previously he had noted a draining sinus on the medial aspect of the first metatarsophalangeal joint, which had persisted for 1 week. Thereafter he remained well until 1 week before admission, when pain, tenderness and local swelling recurred. Three days later a slight purulent discharge was noted. During the 4 days preceding admission the pain, swelling and tenderness became progressively worse and he was referred to the hospital by his physician.

Thirty-five years previously the patient was told that he had heart disease. His only symptom was mild dyspnea on exertion. Fifteen years later, cholecystectomy and appendectomy were done. Otherwise the past history was non-contributory.

Physical examination revealed a well developed and well nourished man who appeared to be acutely ill. The temperature was 101.6°F, the pulse 90, and the respirations 24. The head and neck showed no abnormalities. Excursions of the chest were equal but limited on both sides. The lung fields were resonant, with vesicular breathing throughout. Scattered, fine, moist rales were heard at the bases of both lungs. The heart was slightly enlarged, the left border of dullness being 2 cm outside the midclavicular line. A soft systolic murmur was heard at the apex. The blood pressure was 180/100. The abdomen showed a well healed scar over the right upper rectus muscle but was otherwise normal. The

prostate was small, of normal consistence and nontender. The right foot showed no abnormalities, and the arterial pulsations were normal. On the medial surface of the first metatarsophalangeal joint of the left foot was the opening of a sinus from which a small amount of thin, odorless pus drained. A smear of this material showed the presence of a staphylococcus that was later identified as *Staphylococcus albus*. From the opening of this sinus an area of cellulitis extended over the dorsum of the foot to the level of the malleoli. This area was red, hot and moderately tender. No evidence of lymphangitis was present, although inflammatory edema extended up to the knee. Arterial pulsations could not be identified, although there was a good inflammatory reaction, and the non-inflamed areas were warm, indicating a satisfactory collateral circulation. No enlarged inguinal nodes were palpable.

The specific gravity of the urine varied from 1.010 to 1.022. On admission no albumin was found, but in subsequent specimens it varied from 100 to 190 mg per 100 cc. No sugar was found in the urine in routine or premeal specimens, although the fasting blood sugar was 153 mg per 100 cc. The urine sediment contained no cells at the time of admission, but subsequently as many as 90 to 100 white cells were found per high-power field. The red-cell count was 3,800,000, and the hemoglobin 14.5 gm. The white-cell count was 11,700 with 89 per cent neutrophils. The nonprotein nitrogen was 53 mg per 100 cc on admission, subsequently falling to 28 mg. The total serum protein was 7.3 gm per 100 cc with 5.0 gm of albumin and 2.3 gm of globulin, a ratio of 2:1. The whole blood chloride was 493 mg per 100 cc, expressed as sodium chloride.

X-ray examination of the foot showed calcification in the blood vessels. There was marked decalcification of the bones, but no evidence of osteomyelitis.

Immediately after admission sulfadiazine was begun and the patient received a total of 4 gm. On the evening of the 1st day, however, he suffered a severe chill, followed by a temperature of 104.8°F. Because of the elevated nonprotein nitrogen, sulfadiazine was discontinued and penicillin was begun in doses of 20,000 Oxford units intramuscularly every 4 hours. The inflammation was treated locally with elevation and constant, wet heat. On this regimen the infection localized, and 4 days later incision and drainage was done under local anesthesia. Following drainage the temperature promptly fell to normal, where it remained for 3 days.

On the evening of the 3rd postoperative day, a sudden increase of respirations to 24 was noted and the pulse rose from 80 to 96. The patient complained of lower-abdominal pain. Examination revealed a distended bladder that on catheterization yielded 2220 cc of urine. Until that time the patient had been voiding in large amounts and had had a satisfactory total daily output. Following catheterization the abdominal pain was relieved but the respirations remained elevated. In retrospect it seems likely that the first pulmonary embolus occurred at that time and was followed by acute urinary retention. Repeated examinations of the chest during the following 6 hours showed nothing of diagnostic importance. The legs were carefully examined and showed no tenderness of the calves or thighs. Homans's sign was negative on the right leg but could not be obtained on the left side because of the draining wound over the left ankle.

On the following day the temperature rose to 102.4°F, and during the following 4 days it fluctuated around 101°F. An x-ray film of the chest taken on the day of the first temperature rise showed the lung fields to be clear. The aorta was tortuous and showed some calcification in its arch. The left ventricle was prominent. The chest film was repeated 3 days later and again showed the lung fields to be clear.

Although a pulmonary embolus was strongly suspected and the legs were examined several times daily, it was not until the fifth day after the onset of chest symptoms that tenderness could be elicited in the left calf and over the course of the left femoral vein in the thigh. At that time slight induration was found over the course of the vein, suggesting that the femoral vein, as well as the iliac vein, was solidly thrombosed. Because of the continued fever, associated with an irregular elevation of the respiratory rate, it was believed that the patient had suffered multiple small pulmonary emboli, none of sufficient size to cause a visible change on the x-ray plate.

The patient was immediately transported to the operating room, where the left femoral vein was exposed under local anesthesia. The common femoral vein was opened between

traction ligatures and found to contain an adherent thrombus that completely occluded its lumen. With a large suction tip an effort was made to remove this clot from the common femoral and external iliac veins. A rather large amount was removed, but only a trickle of blood was obtained from the proximal segment, indicating that it extended well into the common iliac vein. The common femoral vein was doubly ligated and divided and the wound closed. In the portion of the femoral vein from which the thrombus was removed it was noted that the intima was destroyed in many small areas so that tiny bits of clot remained adherent, giving it a irregular, patchy appearance. The impression was gained that, had the thrombus been completely removed and a good flow of blood obtained from the proximal segment, the patchy destruction of the intima would have allowed the clot to re-form in the part of the vein proximal to the ligation. The danger of embolism would therefore probably not have been reduced by femoral ligation.

A decision was made to ligate the inferior vena cava. Under spinal anesthesia, supplemented with intravenous Pentothal Sodium, a long right-rectus-splitting incision was made, with its center at the level of the iliac crest. The patient was placed in the Trendelenburg position and the intestine was displaced into the upper abdomen. The posterior parietal peritoneum was incised over the inferior vena cava. There was a considerable amount of fat in this region, and it was with some difficulty that the cava was isolated from the aorta. The duodenum and right ureter were visualized and carefully avoided. A No. 6 nylon ligature was passed around the vena cava at the level of the bifurcation of the aorta. Preoperatively it was intended that the cava should be opened and searched for clot, since clot extending up the inferior vena cava for a distance 12 to 15 cm. has been found,⁷ but shortly before the ligature was applied the patient became restless and cyanotic and it was thought wise to terminate the operation as rapidly as possible. The cava was therefore ligated twice, in continuity, the ligatures being about 1 cm. apart, and the vessel was not opened. No change in pulse or blood pressure was noted at the time the caval lumen was obliterated. The posterior peritoneum was closed with a catgut suture, the intestines replaced, and the abdominal wall repaired. At the beginning of the operation the pulse was 94 and the blood pressure 140/80. At its termination 65 minutes later the pulse was 80 and the blood pressure 85/44. Following operation, elastic bandages were applied to the legs and thighs, the lower extremities were elevated and the patient was placed in an oxygen tent and was given 500 cc of plasma followed by 500 cc of 5 per cent glucose in distilled water intravenously. Immediately following operation profuse perspiration was noted, the extremities were cold, and the patient appeared to be in mild shock. The pulse, however, remained slow, and following the intravenous plasma and glucose the blood pressure returned to 120/85. The profuse perspiration continued for 36 hours, well after other clinical signs of shock had disappeared.

Mottled cyanosis of both legs was noted immediately after operation but was not so marked as in Case 1. Pitting edema of both legs and thighs was evident 4 hours after operation. The edema became most marked 36 hours after operation, after which it gradually subsided and remained absent as long as the patient was confined to bed. As soon as he was allowed out of bed, however, the edema returned, although it became progressively less each day. At the time of discharge only slight edema of the ankles and lower legs was present after the patient had been out of bed for some hours.

For the 4 days preceding caval ligation the temperature had fluctuated between 101 and 103°F. Within 5 hours after ligation the temperature fell to normal, where it remained for the next 36 hours. Beginning on the 2nd and continuing through the 8th postoperative day, the temperature fluctuated between 99 and 101°F, thereafter returning to normal where it remained during the rest of the hospital stay.

Use of the oxygen tent was continued through the first 48 hours after operation while the respirations were labored and rapid. Thereafter the respirations were normal in rate and excursion, and the oxygen was discontinued. The patient was then able to take food and fluids by mouth, so that intravenous medication was also discontinued.

On the 4th postoperative day, the patient was allowed to dangle his legs and the following day was allowed out of bed. In spite of rather marked weakness this activity seemed beneficial and was continued. On the 9th day, a considerable

crease in the amount of edema of the legs was noted. Examination of the abdomen showed a small amount of intraperitoneal fluid. Digitalization, which had been begun at the onset of the respiratory distress 5 days before operation, was continued. By the 12th postoperative day the edema and ascites had become worse and 1 cc of Salvirgan-Theophylline was given intravenously. This was followed by diuresis and diminution of both the ascites and the edema. Because this medication was followed by a chill and fever that lasted for several hours, it was not repeated. With continued activity the ascites gradually disappeared and at the time of discharge from the hospital was entirely gone. The ascites, associated with albuminuria, raised the question whether thrombosis of the inferior vena cava was extending from the site of ligation upward to the region of the renal vessels and possibly beyond. Judging from the subsequent course of events, it is improbable that this occurred.

During hospitalization venous-pressure studies were carried out using small veins on the dorsum of the foot or ankle, simultaneous readings being taken from the right arm. All veins were at the level of the heart when the pressures were recorded. The results of these studies are shown in Table 2.

TABLE 2 Venous-Pressure Readings

NO OF DAYS AFTER OPERATION	VENOUS PRESSURE		
	RIGHT FOOT mm. water	LEFT FOOT mm. water	RIGHT ARM mm. water
3	380	314	78
7	330	292	82
15	300	226	62

The progressive fall in the venous pressure of the feet indicates the rate at which the collateral circulation was established around the point of caval interruption.

Three months after operation the edema of the left leg was minimal and there was no edema of the right leg. All symptoms of obstruction of the bladder neck had disappeared after a prolonged course of stilbestrol,¹⁸ and there was no evidence of ascites. Enlarged veins were noted over the abdomen and chest, being particularly prominent over the lateral aspects.

SUMMARY AND CONCLUSIONS

Ligation of the inferior vena cava below the level of the renal veins, although an operation of some magnitude, is compatible with recovery in seriously ill patients.

Caval interruption is effective in preventing the embolic sequelae of thrombosis of the pelvic veins, whether this thrombosis is primary in the pelvic veins or secondary to a propagating thrombophlebitis originating in the veins of the legs.

Even following ligation of the common femoral veins, an adequate collateral circulation develops around the obstructed cava and peripheral edema eventually disappears.

The indications for ligation of the inferior vena cava are briefly discussed.

Two cases are presented in which caval interruption effectively prevented further pulmonary infarction. The operation was followed by complete recovery in each case.

The postoperative course in these cases is presented in some detail. The following points were most helpful in sustaining the patient through the critical postoperative period: swathing the feet, legs and thighs tightly in elastic bandages to help prevent shock due to the rapid withdrawal of edema fluid from the circulation, the early use of oxygen, and adequate intravenous infusions of plasma and whole blood.

THE HAZARD OF TRANSFUSION MALARIA AFTER THE WAR

A DANIEL RUBENSTEIN, M D,* MAURICE H SHULMAN, M D,† AND DUDLEY MERRILL, M D‡

BOSTON

ACCIDENTAL malaria subsequent to blood transfusion has not been a frequent occurrence in nonendemic areas. Since 1929 only 12 such cases have been reported to the Massachusetts Department of Public Health. In some other parts of the globe this route of transmission is more frequent. In Peiping, China, for example, Wang and Lee¹ reported 54 cases of malaria complicating 3700 transfusions over a period of ten years. Thoroughman,² working in Kiangsu, China, where malaria is encountered throughout the year, reported 45 cases of malaria after the administration of whole blood to 104 patients. In such endemic areas it is practically impossible to exclude mosquito

It is extremely likely that unless certain precautions are observed the situation after the war with reference to the paucity of malarial cases following transfusion will be considerably altered. In the first place, familiarity with the technic of administering whole blood as well as some of its derivatives has been acquired by large numbers of physicians serving with the armed forces. Furthermore, the available supply of whole blood in civilian hospital banks has increased tremendously during the war emergency.

At the conclusion of the war, large numbers of men will return to this country from regions in which malaria is endemic. A certain proportion of

transmission in cases occurring after transfusion. Furthermore, consideration must be given in these localities to the possibility of a previously unrecognized latent infection as the cause of manifest malaria after a transfusion.

In nonindigenous areas where insect-borne malaria is exceedingly rare, difficulties of this sort are not encountered in the diagnosis of post-transfusion malaria. In Massachusetts, since 1930, the possibility of insect transmission within the Commonwealth was present in only 11 reported cases of malaria.³ Since 1938, not a single naturally acquired infection has originated in Massachusetts, but from 1939 to 1944 half the 12 post-transfusion cases were reported. This suggests that during the last six years the risk of acquiring malaria in Massachusetts by a blood transfusion has been greater than that by the natural route of infection. It is therefore apparent that observations in Massachusetts concerning accidental transmission as the result of transfusion are highly reliable.

these persons will continue to harbor malarial parasites in the blood as the result of either clinical or subclinical infection. Although an increase of insect-borne malaria is not anticipated in this climate following the return of these men,⁴ it is conceivable that if such discharged veterans are used indiscriminately as whole-blood donors an increased incidence of post-transfusion malaria will be the result.

To re-emphasize the hazard of acquiring malaria as a result of either the intravenous or the intramuscular administration of whole blood, this paper will review the Massachusetts cases infected in this manner. In addition, the clinical and epidemiologic data concerning 2 of the more recent cases will be presented in detail.

SUMMARY OF CASES

The organisms identified in the blood smears of the 12 recipients were reported as follows: *Plasmodium malariae*, 9, *P. vivax*, 2, and type not stated, 1 (Table 1). The predominance of the quartan variety was striking. The clinical charts of all the cases except one demonstrated regularly recurring paroxysms every seventy-two hours. In Case 12,

that of a four-month-old child who developed malaria after several intramuscular injections of whole blood, the temperature rose every third day, with a low-grade fever intervening. It is well known that in infants and very young children the paroxysms may not be so clearly defined as they are in adults. Although the specific variety of plasmodium was not determined in this case, the long period of latency in the donor suggests that this, too, was quartan malaria.

The interval between the transfusion and the onset of symptoms in the recipient varied from ten days in Case 10 (tertian malaria) to one hundred and eleven days in Case 8 (quartan malaria). In the only other case of tertian malaria the incubation period was twenty-one days. Of the 8 quartan cases in which the incubation period could be determined, in 5 at least forty-two days elapsed before the first evidence of infection in the recipient. The patient in Case 5 received a series of transfusions for a period of several weeks before coming down with malaria, for this reason the incubation period could not be established.

The ages of the recipients varied from four months to sixty-one years. Seven patients were females, and 5 were males.

The ability of transfused blood to produce malaria is an indication of latency of infection in the donor. The total duration of latency is often difficult to establish. If the donor continues to reside in an endemic area subsequent to clinical malaria, the possibility of reinfection at a later date cannot be ruled out. Whether or not the donor presents a past history of malaria while living in an indigenous region, the duration of residence in a new country where insect transmission does not exist or is exceedingly rare may be regarded as the known period of latency. According to such a criterion, the known period of latency was established in 5 donors and varied from twelve to twenty-seven years (Table 1). Not one of these donors had a past history of manifest malaria.

Three additional donors presented a past history of malaria — one five years before infecting the recipient, the second ten years, and the third eighteen years. Because the duration and actual place of residence in the United States after being in an endemic region was not determined for these cases, the known period of latency could not be stated.

Of the 12 donors involved in this study, 10 had lived for a period of years in a country where malaria is known to be endemic (Table 1) — 3 in Italy, 2 in Greece and 1 each in Albania, China, Palestine, Panama and Roumania. In the other 2 cases, information concerning the donor's country of residence was not available.

Attempts to demonstrate malarial parasites in blood smears of the donor were made in 7 cases but were successful in only 2 (Cases 7 and 12). In most of these, both thick and thin smears were

examined. In 3 cases efforts to identify the plasmodium were unsuccessful in spite of splenic massage and the administration of adrenalin.

CASE REPORTS

CASE 1 M E, a 61-year-old native-born man, was admitted to the hospital on December 12, 1944, complaining of chills and fever of 3 weeks' duration. On October 16, a large tumor (cavernous hemangioma) had been removed from his back at another hospital. During the course of the operation and shortly thereafter the patient received several transfusions. He left the hospital on October 25. On October 30 he was readmitted because of sepsis in the operative wound. Healing occurred after incision, drainage and treatment with penicillin. He was discharged on November 14. On November 22 he began having daily chills, followed by sweats, usually late in the afternoon or evening. During the attacks he complained of severe headache.

The temperature on admission was 98.9° F, the pulse 72, and the respirations 18. Physical examination revealed a well-healed scar on the back where the tumor had been removed. There were no other unusual findings.

On December 13 the red-cell count was 4,240,000 and the hemoglobin, 81 per cent. The white-cell count was 5900, with 56 per cent neutrophils and 44 per cent lymphocytes. A blood culture on December 14 was negative, and a series of blood smears on December 13 and December 14 were positive for *P. malariae*. This was confirmed by the State Diagnostic Laboratory. X-ray examination of the chest showed evidence of chronic bronchitis in both lungs. Urinalysis was negative.

At least one paroxysm occurred each day, usually in the evening, from the day of admission until December 16. Antimalarial therapy with 1½ gr of atabrine three times daily was instituted on December 14. On December 16, 5 gr of quinine sulfate was also given the patient receiving this combination of drugs three times daily for the rest of the hospital stay. The temperature during the paroxysms varied from 100 to 101.4° F. Following treatment with quinine and atabrine the paroxysms disappeared. The temperature was 100° F on the morning of December 16, and except for a slight rise to 99.6° F in the evening of December 17 was normal thereafter. Antimalarial therapy was continued for an additional 4 weeks. Convalescence was uneventful, and the patient was discharged on December 20.

During the initial admission for the operation the patient received six transfusions, of which four were whole blood and two were plasma. It was determined that the donor for the transfusion given on October 20 had had an illness of 3 or 4 weeks' duration while living in Panama 20 years previously. The outstanding feature of this illness comprised recurrent paroxysms of chills and sweats. Physical examination of this donor revealed a palpable spleen. Thin and thick blood smears were examined after the injection of 1 cc. of adrenalin. Malarial parasites could not be found. Residence in an endemic country was denied by each of the other donors.

No cases of malaria had been reported from the recipient's community of residence for 15 years.

CASE 2 J K, a 3-year-old, native-born boy, visited his physician on October 17, 1944, with complaints of recurrent paroxysms of fever, chills and sweats every 72 hours for the last 6 weeks. About September 1, his mother noticed that he was not quite well. He was less active than usual and on one or two occasions was feverish. This was followed by the onset of regularly recurring paroxysms of chills and sweats every 3rd day.

The temperature, pulse and respirations were normal at the time of the initial examination. Physical examination revealed a pale, somewhat listless boy. The spleen was felt 3 fingerbreadths below the left costal margin. There were no other abnormal findings.

The patient's mother informed the attending physician that she expected the child to have a chill at 2 p.m. on the afternoon of October 19. One half-hour before this time the doctor visited the patient at his home. At the prophesied time a paroxysm occurred. Blood smears were taken immediately before the chill and shortly afterward. These were reported positive for *P. malariae* by the State Diagnostic Laboratory. Antimalarial therapy, consisting of quinine

BOSTON

ACCIDENTAL malaria subsequent to blood transfusion has not been a frequent occurrence in nonendemic areas. Since 1929 only 12 such cases have been reported to the Massachusetts Department of Public Health. In some other parts of the globe this route of transmission is more frequent. In Peiping, China, for example, Wang and Lee¹ reported 54 cases of malaria complicating 3700 transfusions over a period of ten years. Thoroughman,² working in Kiangsu, China, where malaria is encountered throughout the year, reported 45 cases of malaria after the administration of whole blood to 104 patients. In such endemic areas it is practically impossible to exclude mosquito

It is extremely likely that unless certain precautions are observed the situation after the war with reference to the paucity of malarial cases following transfusion will be considerably altered. In the first place, familiarity with the technic of administering whole blood as well as some of its derivatives has been acquired by large numbers of physicians serving with the armed forces. Furthermore, the available supply of whole blood in civilian hospital banks has increased tremendously during the war emergency.

At the conclusion of the war, large numbers of men will return to this country from regions in which malaria is endemic. A certain proportion of

transmission in cases occurring after transfusion. Furthermore, consideration must be given in these localities to the possibility of a previously unrecognized latent infection as the cause of manifest malaria after a transfusion.

In nonindigenous areas where insect-borne malaria is exceedingly rare, difficulties of this sort are not encountered in the diagnosis of post-transfusion malaria. In Massachusetts, since 1930, the possibility of insect transmission within the Commonwealth was present in only 11 reported cases of malaria.³ Since 1938, not a single naturally acquired infection has originated in Massachusetts, but from 1939 to 1944 half the 12 post-transfusion cases were reported. This suggests that during the last six years the risk of acquiring malaria in Massachusetts by a blood transfusion has been greater than that by the natural route of infection. It is therefore apparent that observations in Massachusetts concerning accidental transmission as the result of transfusion are highly reliable.

these persons will continue to harbor malarial parasites in the blood as the result of either clinical or subclinical infection. Although an increase of insect-borne malaria is not anticipated in this climate following the return of these men,³ it is conceivable that if such discharged veterans are used indiscriminately as whole-blood donors an increased incidence of post-transfusion malaria will be the result.

To re-emphasize the hazard of acquiring malaria as a result of either the intravenous or the intramuscular administration of whole blood, this paper will review the Massachusetts cases infected in this manner. In addition, the clinical and epidemiologic data concerning 2 of the more recent cases will be presented in detail.

SUMMARY OF CASES

The organisms identified in the blood smears of the 12 recipients were reported as follows: *Plasmodium malariae*, 9, *P. vivax*, 2, and type not stated, 1 (Table 1). The predominance of the quartan variety was striking. The clinical charts of all the cases except one demonstrated regularly recurring paroxysms every seventy-two hours. In Case 12,

*District health officer, Massachusetts Department of Public Health, assistant in epidemiology, Harvard School of Public Health.
†Assistant pediatrician, Salem Hospital; associate pediatrician, North Shore Babies Hospital, Salem.
‡Junior visiting physician, Boston City Hospital; visiting physician, Pondville Hospital, Wrentham; assistant physician, Cambridge Hospital.

that of a four-month-old child who developed malaria after several intramuscular injections of whole blood, the temperature rose every third day, with a low-grade fever intervening. It is well known that in infants and very young children the paroxysms may not be so clearly defined as they are in adults. Although the specific variety of plasmodium was not determined in this case, the long period of latency in the donor suggests that this, too, was quartan malaria.

The interval between the transfusion and the onset of symptoms in the recipient varied from ten days in Case 10 (tertian malaria) to one hundred and eleven days in Case 8 (quartan malaria). In the only other case of tertian malaria the incubation period was twenty-one days. Of the 8 quartan cases in which the incubation period could be determined, in 5 at least forty-two days elapsed before the first evidence of infection in the recipient. The patient in Case 5 received a series of transfusions for a period of several weeks before coming down with malaria, for this reason the incubation period could not be established.

The ages of the recipients varied from four months to sixty-one years. Seven patients were females, and 5 were males.

The ability of transfused blood to produce malaria is an indication of latency of infection in the donor. The total duration of latency is often difficult to establish. If the donor continues to reside in an endemic area subsequent to clinical malaria, the possibility of reinfection at a later date cannot be ruled out. Whether or not the donor presents a past history of malaria while living in an indigenous region, the duration of residence in a new country where insect transmission does not exist or is exceedingly rare may be regarded as the known period of latency. According to such a criterion, the known period of latency was established in 5 donors and varied from twelve to twenty-seven years (Table 1). Not one of these donors had a past history of manifest malaria.

Three additional donors presented a past history of malaria — one five years before infecting the recipient, the second ten years, and the third eighteen years. Because the duration and actual place of residence in the United States after being in an endemic region was not determined for these cases, the known period of latency could not be stated.

Of the 12 donors involved in this study, 10 had lived for a period of years in a country where malaria is known to be endemic (Table 1) — 3 in Italy, 2 in Greece and 1 each in Albania, China, Palestine, Panama and Roumania. In the other 2 cases, information concerning the donor's country of residence was not available.

Attempts to demonstrate malarial parasites in blood smears of the donor were made in 7 cases but were successful in only 2 (Cases 7 and 12). In most of these, both thick and thin smears were

examined. In 3 cases efforts to identify the plasmodium were unsuccessful in spite of splenic massage and the administration of adrenalin.

CASE REPORTS

CASE 1 M E, a 61-year-old native-born man, was admitted to the hospital on December 12, 1944, complaining of chills and fever of 3 weeks' duration. On October 16, a large tumor (cavernous hemangioma) had been removed from his back at another hospital. During the course of the operation and shortly thereafter the patient received several transfusions. He left the hospital on October 25. On October 30 he was readmitted because of sepsis in the operative wound. Healing occurred after incision, drainage and treatment with penicillin. He was discharged on November 14. On November 22 he began having daily chills, followed by sweats, usually late in the afternoon or evening. During the attacks he complained of severe headache.

The temperature on admission was 98.9° F, the pulse 72, and the respirations 18. Physical examination revealed a well-healed scar on the back where the tumor had been removed. There were no other unusual findings.

On December 13 the red-cell count was 4,240,000 and the hemoglobin, 81 per cent. The white-cell count was 5900, with 56 per cent neutrophils and 44 per cent lymphocytes. A blood culture on December 14 was negative, and a series of blood smears on December 13 and December 14 were positive for *P. malariae*. This was confirmed by the State Diagnostic Laboratory. X-ray examination of the chest showed evidence of chronic bronchitis in both lungs. Urinalysis was negative.

At least one paroxysm occurred each day, usually in the evening, from the day of admission until December 16. Antimalarial therapy with 1½ gr of atabrine three times daily was instituted on December 14. On December 16, 5 gr of quinine sulfate was also given the patient receiving this combination of drugs three times daily for the rest of the hospital stay. The temperature during the paroxysms varied from 100 to 101.4° F. Following treatment with quinine and atabrine the paroxysms disappeared. The temperature was 100° F on the morning of December 16, and except for a slight rise to 99.6° F in the evening of December 17 was normal thereafter. Antimalarial therapy was continued for an additional 4 weeks. Convalescence was uneventful, and the patient was discharged on December 20.

During the initial admission for the operation the patient received six transfusions, of which four were whole blood and two were plasma. It was determined that the donor for the transfusion given on October 20 had had an illness of 3 or 4 weeks' duration while living in Panama 20 years previously. The outstanding feature of this illness comprised recurrent paroxysms of chills and sweats. Physical examination of this donor revealed a palpable spleen. Thin and thick blood smears were examined after the injection of 1 cc of adrenalin. Malarial parasites could not be found. Residence in an endemic country was denied by each of the other donors.

No cases of malaria had been reported from the recipient's community of residence for 15 years.

CASE 2 J K, a 3-year-old, native-born boy, visited his physician on October 17, 1944, with complaints of recurrent paroxysms of fever, chills and sweats every 72 hours for the last 6 weeks. About September 1, his mother noticed that he was not quite well. He was less active than usual and on one or two occasions was feverish. This was followed by the onset of regularly recurring paroxysms of chills and sweats every 3rd day.

The temperature, pulse and respirations were normal at the time of the initial examination. Physical examination revealed a pale, somewhat listless boy. The spleen was felt 3 fingerbreadths below the left costal margin. There were no other abnormal findings.

The patient's mother informed the attending physician that she expected the child to have a chill at 2 p.m. on the afternoon of October 19. One half-hour before this time the doctor visited the patient at his home. At the prophesied time a paroxysm occurred. Blood smears were taken immediately before the chill and shortly afterward. These were reported positive for *P. malariae* by the State Diagnostic Laboratory. Antimalarial therapy, consisting of quinine

sulfate, was instituted immediately. The paroxysm that was expected on October 22 did not occur. Antimalarial treatment was continued for a period of 5 weeks, during which time there were no recurrences. The spleen gradually diminished in size and was no longer palpable at an examination 2 months after the onset of treatment.

Careful inquiry into the history of this patient revealed that he had received a transfusion of 300 cc of blood from his father on May 12 because of a severe infection of the throat. The father presented no history of malaria. He was born in Albania in 1899 and came to this country in December, 1919. During his 25 years' residence here he had been perfectly well. Thick and thin smears of the donor's blood were negative for *P. malariae*. Adrenalin was not administered.

Malaria had not been reported from the community where this case had occurred for nineteen years.

DISCUSSION

Although quartan malaria in most parts of the world occurs less frequently than either the tertian or estivoautumnal varieties,⁴ it is noteworthy that in this series of 12 cases of post-transfusion infection at least 9 and possibly 10 were caused by *P. malariae*. It is known that the period of latency in tertian infections may endure for about five years and that a single falciparum infection may remain latent for one month to a year.⁴ Evidence of the sort presented in this paper indicates that latency in quartan malaria is of much greater duration.

When the war is over, the majority of malaria carriers returning from endemic areas will harbor *P. vivax*. If such persons are used as whole-blood donors within five years of their return, an increase in post-transfusion malaria of the tertian variety may occur. If large numbers of troops remain indefinitely in endemic areas, the potential supply of tertian carriers who return to this country will remain at a high level for a long time after the war. A rise in tertian cases as a result of accidental transmission may become a serious problem for a period of several years.

This possible increase in incidence in the post-war period may be prevented by rejecting all prospective donors for whole-blood transfusion who have served in endemic malarious regions. Prophylactic administration of quinine or atabrine while in the endemic area or the absence of a history of malaria should not alter this rule. Obviously, when blood is being drawn for plasma this precaution is not essential.

Ackermann and Filatov⁵ and Antschelewitsch⁶ have shown that when blood is stored for a long time plasmodia gradually degenerate and finally disappear. The former investigators, working with psychotic patients, were unable to transmit malaria with whole blood stored in the refrigerator for five days or longer. Antschelewitsch was able to infect persons with whole blood stored for eight days. One of our cases (Case 5) occurred after a series of stored-blood transfusions.

The long interval between the transfusion and the onset of symptoms observed in several of these

cases deserves further comment. Although the incubation period in malaria varies in naturally acquired infections from six to forty days, longer periods have occasionally been reported. In Holland it has been observed that outbreaks each spring are due to infections contracted during the previous autumn.⁷ Schuffner and Schwellengrebel (quoted by Hackett⁴) allowed themselves to be bitten by infected mosquitoes in the fall and had their onset eight or nine months later. It may be postulated that the prolonged incubation period noted in several of our patients was due to the relatively small number of parasites in the circulating blood after a long period of latency.

Because several weeks may elapse between the transfusion and the onset of malaria in the recipient, the causal relations of these events may not be recognized. Stein⁸ reported a case in which such an association was not realized after the transfusion of a girl with blood from her father. The patient recovered after treatment with quinine. Following a second transfusion from the same donor, she again became ill with malaria. At that time it was discovered that the father had had malaria eight years previously, and parasites were demonstrated in his blood after the second transfusion.

Post-transfusion malaria when recognized and promptly treated is not usually fatal. It is an infection that may be prevented by properly selecting donors for blood transfusion. Simply by exercising care in this respect, an increase in the incidence of post-transfusion malaria after the war can be prevented.

SUMMARY

Since 1929, of 12 cases of post-transfusion malaria reported in Massachusetts, 9 were quartan, 2 tertian, and 1 undetermined.

The predominance of quartan infections is evidence that in a nonendemic area the problem of post-transfusion malaria is intimately linked with the ability of *Plasmodium malariae* to remain latent for long periods of time.

Because of the absence of insect-borne transmission in a nonendemic area, latency may be determined with a greater degree of accuracy in such an area than in an endemic one in which reinfection is difficult to exclude.

The widespread use of whole-blood transfusions in medical practice and the return to this country of large numbers of carriers from endemic areas may act together to increase the hazard of accidental transmission of malaria in the post-war period.

An increased incidence of tertian malaria as a result of accidental transmission may be prevented after the war by eliminating prospective donors for whole-blood transfusions who have lived in endemic areas.

CLINICAL NOTE

GASTROSCOPIC STUDIES IN NAVAL PERSONNEL WITH CHRONIC SEASICKNESS*

EDWARD B. BENEDICT M.D.,† AND LIEUTENANT COMMANDER ROBERT S. SCHWAB (MC), U.S.N.R.

In a group of 150 cases of chronic seasickness studied clinically at the United States Naval Hospital in Chelsea, Massachusetts,^{1,2} routine gastrointestinal x-ray studies showed that 50 per cent had a characteristic roentgenologic appearance.³ These cases showed a constant triad of findings, namely, hypersecretion, loss of gastric motility and spasm of the pylorus. In a few cases there was in addition evidence of a moderate degree of hypertrophic gastritis, seen when a thick barium solution was used to bring out the gastric rugae.

It was considered highly desirable to confirm these findings by direct gastroscopic examination. Since facilities for this examination were not available at the naval hospital, it was performed at the Gastroscopic Clinic of the Massachusetts General Hospital. The patients did not receive breakfast or lunch on the day of the examination and were usually given 0.1 gm. of Nembutal on leaving the naval hospital, so that a mild degree of relaxation was possible when they reached the civilian clinic. They were for the most part examined within five days of being sent ashore from the small vessels on which they had been seasick. They had had from four to six weeks of protracted seasickness, with extreme vomiting, weight loss and a decrease in efficiency.

The results of gastroscopic examination in 22 men showed moderate hypertrophic gastritis (1 case), moderate superficial gastritis (2 cases), slight superficial gastritis (3 cases), gastric spasm without gas-

tritis (2 cases) and a normal stomach (14 cases). As pointed out by Benedict and Mallory,⁴ superficial gastritis as described by the gastroscopist corresponds to the acute exudative gastritis of the pathologist. Hypertrophic gastritis as described gastroscopically corresponds to an exaggerated form of the physiologic plasma-cell and lymphocytic infiltration of the normal stomach (chronic gastritis).

Most of the patients were under twenty-five years old, an age group in which one would expect to find a comparatively normal gastric mucosa. Although a series of 22 cases is too small a one from which to draw any final conclusions, the finding of a normal stomach in 14 of them indicates that seasickness does not usually cause changes in the gastric mucosa.† The only patient showing any degree of chronic (hypertrophic) gastritis was a man of forty-one who had suffered mild seasickness before joining the Navy and had then suffered two months of severe perpetual seasickness. Two other patients had spasm without gastritis, and 3 of the remaining 5 showed only slight superficial gastritis, which in 2 cases was confined to a small area. In 1 of the latter cases, re-examination six weeks later revealed a normal stomach. Of the 2 patients who showed moderate superficial gastritis, 1 was a habitual user of alcohol. Hence, the thickened rugae observed by x-ray examination in many of these cases were not confirmed by gastroscopy and cannot be considered as positive evidence of gastritis.

CONCLUSION

Although 50 per cent of cases of chronic seasickness present x-ray evidence of hypersecretion, loss of gastric motility and spasm of the pylorus, as well as thickened gastric rugae in some, the gastroscopic picture is usually essentially normal.

MEDICAL PROGRESS

PRACTICAL ASPECTS OF OXALATE METABOLISM (Concluded)*

HAROLD JEGHERS, M D,† AND ROSEMARY MURPHY, M D ‡

BOSTON

OXALATE LITHIASIS

Urinary lithiasis is a broad subject. There are a number of excellent general papers that are of considerable value for the purpose of orientation in this complex field.⁸²⁻⁸⁹ There has been an increasing interest in recent years in the pathogenesis of urinary calculi. Many factors, such as hyperparathyroidism, persistent hypercalciuria, urinary-tract stasis, a persistently alkaline urine, infection

stone is well shown in Table 2, which is based on the chemical analysis of stones as reported by several authorities.⁹¹⁻⁹⁶ Barney and Jones⁸⁸ state that from 1936 to 1940 analysis of stones removed at operation or passed spontaneously at the Massachusetts General Hospital showed phosphates in 59 per cent and oxalates in 33 per cent. Burkland⁹⁰ reports that among 112 cases of urinary-tract calculi analyzed at the Brady Urological Institute the

TABLE 2 Frequency of Various Types of Urinary Calculi *

TYPE OF STONE	RANDALL ⁹⁵		KRETSCHMER ⁹⁴	LA TOWERS ⁹⁶	McINTOSH ⁹¹
	KIDNEYS	URETER	URETER	ENTIRE URINARY TRACT	ENTIRE URINARY TRACT

Miscellaneous pure stones			2	6	
Mixed stones	80	59		72	
Totals	151	159	102	150	100

*The classification of stones varied with each author. Pure stones were generally considered to be those with a predominance of one or in some cases two elements. McIntosh's classification is chiefly based on the presence or absence of the metallic elements.

†Magnesian stones contain not only calcium carbonate and calcium phosphate but also magnesium and ammonium.

of the urinary tract with urea-splitting organisms and prolonged recumbency, have been established as causes of phosphate calculi. Furthermore, the prevention of their recurrence and even their dissolution by chemical means have had some measure of success. By contrast, the pathogenesis and therapy of oxalate calculi remain enigmatic. Burkland⁹⁰ has given the best modern appraisal of the problem. This paper and those by McIntosh⁹¹ and Hammarsten⁹²⁻⁹³ should stimulate a renewed interest in oxalate calculi.

One of the most important aspects of oxalate metabolism is its role in the causation of calculi in the urinary tract. Oxalate stones occur both in a relatively pure form as calcium oxalate and as mixed stones. They are exceedingly frequent and are therefore of considerable clinical interest. Their frequency as contrasted with that of other types of

were 62 in which the stones were composed of pure calcium oxalate or of calcium oxalate and phosphate. Thompson et al.⁹⁷ report that the quantitative chemical analysis of urinary calculi in 47 cases revealed 78 per cent to be of the calcium oxalate-phosphate type, with the heavy calculi containing more phosphate and those of light weight relatively richer in oxalate. It thus appears that in the United States more than 30 per cent of all stones of the urinary tract are of oxalate origin. The incidence of mixed oxalate stones is high, since calcium oxalate occurs in acid urine in association with uric acid and urates and in alkaline urine with amorphous phosphates. Predominant calcium oxalate stones develop only in acid urine.^{90, 91} Because of their frequent small size oxalate stones often enter the ureter and make up a large percentage of ureteral stones. Because of their rough surface they frequently cause colic and hematuria. In the so-called "stone belt" of Central Europe (see below) the percentage of oxalate stones is said to reach 65 per cent of all urinary tract calculi.^{98, 99}

Oxalate calculi occur in several forms¹⁰⁰⁻¹⁰²—as small, smooth, round or faceted stones, not larger

*From the Evans Memorial, Massachusetts Memorial Hospitals, the Fifth and Sixth (Boston University) Medical Services, Boston City Hospital, and the Department of Medicine, Boston University School of Medicine.

†Associate professor of medicine, Boston University School of Medicine, physician-in-chief, Fifth Medical Service, Boston City Hospital, and assistant physician, Clinical Staff, Evans Memorial, Massachusetts Memorial Hospitals.

‡Formerly, outpatient physician, Boston City Hospital, and assistant in medicine, Boston University School of Medicine.

than a pea and usually found in the renal pelvis or ureter, as "mulberry calculi," so named because of mammillary processes on their surfaces, of larger size and more frequent in the bladder, as those of so-called "jackstone shape," a rare type with projecting spurs, seen in the bladder, and as crystalline calculi, small stones with their surfaces completely covered with sharp, glistening crystals, which are exceedingly irritating. Many of the small oxalate stones passed naturally or found at operation in persons with uninfected urine are of the last type. In contrast to those composed of calcium phosphate and cystine, staghorn calcium oxalate calculi are rare.

Calcium oxalate calculi are extremely dense and readily demonstrable on a K U B roentgenogram. The roentgen appearance of spicules radiating from a central focus is seen at times and is pathognomonic of this type of calculus (see illustration^{93 101}). According to the Schinz experiment, as tabulated by Morrison,¹⁰² the relative densities of urinary calculi on roentgen-ray examination are water and body tissue, 1, xanthine, 1.2, urates, 1.38, cystine, 3.7, ammonium magnesium phosphate, 4.1, calcium oxalate, 10.8, calcium carbonate, 15.0, and calcium phosphate, 22.0. Others rate calcium oxalate as the densest of all.^{90 100}

Heredity is not generally considered a factor in the pathogenesis of oxalate calculi. Nevertheless, there are isolated papers in which this possibility is considered. Gram¹⁰³ has reported the study of five generations of a family in which calcium oxalate urinary concretions occurred with great frequency. This predisposition to form calculi was apparently inherited dominantly but showed itself clinically almost exclusively in males.

Oxalate calculi may occur in acid, neutral or alkaline urine and remain insoluble in either acid or alkaline urine. It is also generally agreed that neither stasis nor infection of the urinary tract predisposes to the formation of calcium oxalate stones. This is in sharp contrast to calcium phosphate calculi.

There are a number of areas in the world where oxalate stones are particularly prevalent. In some of these the calculi appear to be related to a vegetable diet of high oxalic acid content. This is by no means constant, for in other equally prominent stone areas the diet is noticeably low in oxalates.^{89 98-100 104} Here the source of the urinary oxalates appears to be of intestinal or endogenous origin. A most remarkable phenomenon has been noted in the area of Central Europe blockaded during World War I.^{98 99} Starting about 1919, reaching a sharp peak in 1924 and remaining sustained until at least 1937, there was a striking increase in the incidence of oxalate stones, at times reaching ten times the usual incidence. Oxalate stones were said to constitute 65 to 90 per cent of all stones studied by urologists in this area. The stones were

small, renal in origin, often

and frequent in middle-aged

only infrequently. A careful ana-

etiologic factors led Grossmann^{98 99} to co-

the basic cause remained obscure. Wins-

White¹⁰⁵ suggested that a dietetic fault seemed

highly probable. Hammarsten's^{92 93} experimental

production of oxalate stones in rats on a diet low in

magnesium is a new concept that may possibly shed

some light on the reason for this stone wave. The

magnesium content of foods varies with the content

of this element in the soil. Prevention of its depletion

from the soil in turn depends on the agricultural

methods and type of fertilizer used.¹⁰⁶

Whether or not this can predispose toward human

oxalate lithiasis remains to be proved.

Many attempts have been made to associate

oxalate stones with oxaluria. Although this may in

general be true, it appears that oxaluria may per-

sist for years without oxalate stones' developing,

and conversely that oxalate stones are not always

associated with hyperoxaluria or demonstrable

oxalate crystals in the urine. The many factors in-

creasing the oxalate content of urine are discussed

below. It is not clear what role these have in the

production of oxalate stones. It has been stated

that persons with oxalate stones after eating foods

rich in oxalic acid occasionally show either an un-

usually high blood and urine oxalate content or one

less than the normal supply.⁹⁰ Such inconsistent

results make evaluation of this factor difficult.

Calcium oxalate in the normal urine is usually

supersaturated — from two and a half to three

and a half times at a pH of 5.5, according to Las-

sen,¹⁰⁷ to as much as six- to eightfold according

to others.^{100 106} Hydrotropic and colloidal sub-

stances present in the urine are undoubtedly respon-

sible for at least part of this increased solubility of

calcium oxalate as compared with its solubility in

distilled water. The influence of urea in increasing

the solubility of calcium oxalate in water is illus-

trative of this mechanism.^{108 109} It is therefore pos-

sible that the formation of oxalate stones depends

more on decreased solubility due to some disturbance

in such a protective colloidal mechanism than on

an absolute increase of urinary excretion of oxalates.

Unfortunately, but little is known concerning the

factors controlling the protective colloidal mecha-

nism. Furthermore, the primary role of this mecha-

nism has recently been questioned.⁹¹

The crystals formed in a colloid menstruum *in vitro*

differ from those of the same substance formed in a

watery solution.¹¹⁰ Ord and Shattock¹¹¹ showed

many years ago that the so-called "coalescent

forms" of oxalate crystals constituted the structural

units of oxalate calculi as seen microscopically.

Lassen¹⁰⁷ administered to patients a saline solu-

tion containing calcium, magnesium and phosphate

(Hammarsten's mixture) and a solution of sodium

chloride and magnesium chloride, with promotion of

diuresis and diminution in concentration of oxalate and an increase in magnesium and calcium in the urine. Consequently, the urine became less saturated with calcium oxalate. The therapeutic implication of this observation remains to be determined.

Small calcium oxalate stones with a single faceted area suggesting attachment and development from a primary lesion on a renal papilla have been noted on occasion.^{105, 112, 113} Although this may explain their origin, the continued growth of calculi apparently depends on other factors.

Much interest has been aroused in recent years in the relation of citric acid metabolism to renal calculi and the possible therapeutic value of the use of citrate or agents that control its urinary excretion in the management of calculi,¹¹⁴⁻¹¹⁷ as well as the use of aluminum hydroxide gels to divert phosphate excretion from the urinary to the intestinal tract.¹¹⁷ Citrate solutions containing magnesium used locally in the urinary tract have successfully dissolved stones.¹¹⁸ These new concepts, however, appear to be related to stones composed of phosphates or carbonates rather than of oxalates.

Oxalate calculi have been produced experimentally in animals. Renal calculi produced by vitamin A deficiency¹¹⁹ are composed of phosphates. The production of an intense artificial hyperoxaluria by administration of oxalic acid esters and salts subcutaneously in a carefully controlled experiment utilizing over 900 rats, Hammarsten^{92, 93} not only produced oxalate calculi but apparently elucidated some pathogenic factors involved. These striking results are worthy of careful attention and, since original papers are not readily accessible, will be discussed in some detail. A magnesium-poor diet induced oxalate stones, with or without an increase in intake of vitamins A and D, but the stones were more numerous with avitaminosis. Oxalates in the diet favored stone formation but was not essential, since calcium oxalate stones formed on an oxalate-free diet. Paradoxically, a diminution in calcium in the food increased elimination of calcium in the urine and was marked when the animal was deficient in calcium.

A low-magnesium, high-oxalate, low-phosphorus diet gave the highest incidence of stones. The stones of the urine of animals with experimental calcium oxalate calculi showed it to be acid with decreased magnesium content. The pH of the urine of these animals was 5.5 to 6.0, if the diet was high in oxalate. The pH of the urine of animals with stones was 6.5 to 7.0.

magnesium intake, which decreased the excretion of calcium oxalate, some ill-defined disturbance in metabolism due to the magnesium deficiency, a negative calcium balance and increased calcium excretion, and the excretion of more oxalic acid was obtained in the diet.

Increase of magnesium in the diet without an increase in vitamins caused a diminution in urinary calcium excretion. A vitamin-deficient diet together with a low calcium intake led to mobilization of calcium from the skeleton, with a negative calcium balance and high urinary calcium excretion. Increasing the amount of calcium in the diet apparently decreased the excretion of oxalic acid, increased the solubility of urinary calcium oxalate, and at the same time diminished urinary elimination of calcium.

Hammarsten also succeeded in decalcifying formed calculi. Animals were kept on the diet producing regime until roentgen-ray study revealed the presence of calculi. The diet was then changed to one rich in calcium, magnesium and all the vitamins. After several months, post-mortem examination of the sacrificed animals showed complete almost complete decalcification of the stones, with the organic matrix still present.

It is well to note that Hammarsten's work is confirmation, and further that it is not only applicable to man. The principles evolved in her experiments are applicable to man. The metabolism of oxalic acid and calcium and the role of the metallic elements in the metabolism of calcium oxalate stones. A great advance in our knowledge of the conditions underlying stone formation. Hammarsten's work is confirmed.

Burkland,⁹⁰ on the basis of available clinical evidence, suggests that the formation of oxalate stones in the urinary tract can be decreased by a well balanced diet, by increasing use of foods of high oxalic acid content, increased intake of vitamins A and B, by a diet of carbohydrates in the diet to cut down on fermentation and the production and absorption of oxalic acid, by eliminating constipation, chronic indigestion and so forth, by avoiding worry, by drinking eight to ten glassfuls of water daily, by eating relatively rich in proteins, by some form of exercise and by eliminating foci of infection. The paper contains a specimen dietary instruction sheet, the suitable for patients, that embodies the aforementioned ideas and a simplified table of oxalic acid content of foods.

Hammarsten,^{92, 93, 120} on the basis of her experiments, has suggested a prophylactic diet.

whole-grain products, a variety of fruits and vegetables (consumed raw or with water used for cooking), milk, butter, meat and meat broth. If necessary, medicinal calcium and magnesium can be used to supplement the diet. Magnesium is present in any natural foods, so that a well-balanced diet could furnish an adequate amount. There may be some loss in water used for cooking. The true value of these prophylactic regimes for preventing the formation of oxalate calculi in human beings remains to be adequately established, but for the present they can be considered to rest on a rational basis. It is well to recall, however, that the results obtained from animal experiments are not always directly applicable to man.

THE METABOLISM OF OXALATES

Blood and Urine Levels

There is considerable variation in the reported values for the normal oxalate content of the blood, as may be seen from Table 3, apparently depending to a great extent on the method used.¹²¹⁻¹³⁰ No attempt will be made to review or compare all the methods. Barrett¹³⁰ has recently evaluated results

TABLE 3 Normal Oxalate Content of the Blood

SOURCE	SPECIES	OXALATE CONTENT mg /100 cc
Merz and Mauger ¹²¹	Man	3.0
	Rabbit	6.0-9.0
Loeper ¹²²	Man	1.0 or less
Jürgens and Spehr ¹²²	Man	5.22-9.72
	Dog	5.40-19.26
Suzuki ¹²⁴	Man	4.0-6.0
Kamiya et al ¹²⁵	?	2.0-4.0
Steinberg and Brown ¹²⁸	Man	5.5-7.5
	Rabbit	4.5-6.0
Leulier and Dorché ¹²⁷	Horse	0.227-0.270
	Ox	0.218-0.276
	Sheep	0.268-0.485
Steinberg et al ¹²⁸	Man	5.0-7.5
Barber and Gallimore ¹²⁹	Man	0.4-0.6
	Rabbit	0.4-0.8
Barrett ¹³⁰	Man	0.23-0.77 (Average 0.48)

obtained by means of the three most widely used procedures, namely, the cerous chloride precipitation method of Izumi, Suzuki¹²⁴ and other Japanese investigators, the lime water precipitation method of Merz and Mauger¹²¹ and the ethyl oxalate procedure of Dodds and Gallimore.¹³¹ He was unable to confirm the high values obtained by the methods of the Japanese workers or of Merz and Mauger; he concluded that the low values obtained by Dodds and Gallimore were of the correct order of magnitude. Furthermore, he cast some doubt that the oxalate obtained by any procedure is entirely pre-existent oxalate, since the mere addition of ascorbic acid to blood prior to the determination increased the oxalate content by 0.025 mg for each 1 mg of ascorbic acid added. Some reported values for the oxalate content of urine are given in Table 4.¹³²⁻¹³⁶ These also are subject to question because of the

lack of reliability of the methods used, although there is a greater uniformity here than in the values reported for blood oxalate.

It is important to bear in mind in any evaluation of the published reports that the results are often open to question and not frequently are invalid.

Oxalate Values in Various Diseases

In addition to the hyperoxalemia and hyperoxaluria reported in the syndrome of oxaluria, there are numerous references to elevations in a variety of

TABLE 4 Normal Oxalate Content of the Urine

SOURCE	SPECIES	OXALATE CONTENT mg /24 hr
Loeper ¹²²	Man	20.0 mg (per liter)
Borgström ¹³²	Guinea pig	0.57-0.87
Herkel and Koch ¹³²	Rabbit	5.0-15.0
	Man	21.5 (average)
Müller ¹³³	Man(?)	20.0-40.0
Widmark ¹³⁴	Man	14.0-56.0
Okawa ¹³⁵	Rabbit	5.6-15.9
Adolph and Liang ¹³⁶	Rat	1.0
Barrett ¹³⁰	Man	20.0-47.0 (Average, 33 mg)

unrelated diseases. These reports are found almost entirely in the foreign literature, much of which is not available. Consequently, no attempt has been made to review this subject completely. References are made merely to certain illustrative papers to indicate the apparent wide scope of the subject.

Jürgens and Spehr¹²² found blood oxalate values elevated in diseases of the liver, with a tendency to parallel the serum bilirubin level. Pennetti¹³⁷ reported similar clinical findings and experimentally produced hyperoxalemia in rabbits and dogs by ligation of the common bile ducts. Herkel and Koch¹³² found high urinary values in a patient with cirrhosis of the liver without jaundice who was being maintained on a high-carbohydrate diet. In addition, they demonstrated that the ingestion of 600 to 800 gm of spinach (equivalent to 3 or 4 gm of oxalic acid) by 2 patients, one with cirrhosis of the liver with ascites and the other with cirrhosis with jaundice, caused a marked elevation in urinary oxalate content. This they attributed to an elevation in blood oxalate, although they made no determinations on the blood.

Scaglioni¹³⁸ found the blood oxalate level of patients with compensated cardiac disease to be normal. With development of edema and oliguria the blood level rose and the urinary excretion became relatively greater, although the total daily output was unaffected. With improvement of the cardiac status under routine therapy the blood oxalate values returned to normal. Loeper et al¹³⁹ noted similar findings in patients with varying degrees of cardiac failure. Simultaneously determined values for urinary oxalate convinced them that the oxalemia could not be explained on the basis of renal insufficiency.

Scaglioni¹⁴⁰ also investigated the level of blood and urine oxalates in various types of renal disease, with and without insufficiency. He found no variations from normal when renal function was normal, as tested by the blood nonprotein nitrogen and by concentration and dilution tests. With renal insufficiency the blood oxalate became elevated, but the urinary values varied from low to normal to high. If improvement occurred, however, the urinary oxalate increased as the blood oxalates returned to normal. Although the oxalate level of the blood tended to be high, it did not exactly parallel the intensity of the clinical manifestations. Khouri^{141, 142} and Jürgens and Spehr¹²² have reported hyperoxalemia, and Herkel and Koch¹³² have noted hyperoxaluria, in uremia.

A number of investigators^{122, 123, 143-145} report that diabetes mellitus is associated with hyperoxalemia oxaluria or both. Herkel and Koch¹³² however, were unable to find any relation between the urinary values for glucose and those for oxalic acid. The blood oxalate values parallel the blood sugar values and respond to insulin in a similar manner.

In addition, deviations from normal values have been noted in certain severe diseases of the central nervous system,¹⁴⁶ chronic nongouty arthritis,¹⁴⁷ gouty arthritis,¹⁴⁷ severe anemias¹⁴² and leukemia.¹⁴²

Source of Blood and Urine Oxalates

The oxalate of the blood and urine is derived from several sources not all of which have been adequately proved. The largest and best understood source is oxalate pre-existent in food. The oxalate content of certain foodstuffs has been listed in Table 1. This is present as insoluble calcium oxalate, as soluble sodium or potassium oxalate and in very slight amounts as oxalic acid. The calcium oxalate is relatively insoluble, is absorbed from the intestinal tract with great difficulty and is largely excreted in the feces. The degree to which it is absorbed is thought to be related to the gastric acidity and may be increased in the presence of hyperchlorhydria. Herkel and Koch¹³² studied the oxalate excretion in the urine after the administration of spinach. In normal persons increase occurred during the six hours following ingestion, but this response could be diminished by atropine and greatly enhanced by histamine. Patients with achlorhydria failed to show oxaluria after ingestion of spinach and were uninfluenced by histamine, but developed oxaluria if hydrochloric acid was administered with the spinach. From this they concluded that gastric acidity is an important factor in determining the degree of absorption of oxalates from the gastrointestinal tract. The soluble oxalates present in foods may be absorbed as such or be changed to insoluble calcium oxalate by combination with calcium in the diet. Thus, it has been demonstrated that the addition of milk, calcium chloride or calcium carbonate to the diet prevents the oxaluria

that follows the ingestion of an oxalate-rich food. It is important to emphasize that the oxalic acid values listed in Table 1 are figures for total oxalates expressed as oxalic acid. They do not differentiate the relative proportions of readily absorbable or difficultly absorbable forms, and are therefore not necessarily indicative of ability to elevate the blood or urine oxalate levels.

In addition to preformed oxalate it has been suggested that certain foodstuffs are potential sources, since oxalates may be intermediary products in their metabolism (the so-called "oxaligenic foods of Loeper"). Of these the most important are carbohydrates, especially glycogen and starches (Loeper,⁸ Loeper et al.¹⁴³ and Oikawa¹⁴⁸). Pure protein—for example, gelatin and plasma—and fats are not considered as precursors of oxalate, but meat and foods rich in connective tissue rank next to carbohydrate. Herkel and Koch¹³² studied 11 patients on an oxalate-poor diet with a constant protein and varying carbohydrate and fat content. The results were not constant, but patients tended to have greater urinary oxalate excretion on high-carbohydrate diets than on low-carbohydrate ones. Jürgens and Spehr¹²² studied the blood sugar and oxalic acid levels of normal patients after the oral administration of glucose. They found that the blood oxalate level tended to parallel the glucose level. The peak was reached somewhat earlier on the oxalate curve, and the decline was somewhat slower. They suggested that the oxalemia reported to be present in many patients might be explained on a basis of low sugar tolerance.

Second to the oxalate of food (actual or potential), the metabolic processes of certain intestinal bacteria and parasites have been emphasized as sources of oxalate. Loeper et al.¹⁴³ refer to experiments by various observers that demonstrate the formation of oxalic acid during *in vitro* studies on species of *Aspergillus* and *Mucor* and on the colon bacillus. Finck¹⁴⁹ credits Guidiceandrea with establishing in 1933 for the first time a relation between intestinal parasitosis and oxaluria. He suggests that "toxins" from the parasites interfere with the metabolism of the liver and thereby cause hyperoxalemia. Khouri¹⁴¹ finds blood oxalates to be elevated frequently in patients with filariasis and bilharziasis, and postulates that a "toxin" diminishes the oxalolytic action of the liver. A relation between oxaluria and amebic dysentery has been emphasized.⁸³ Loeper⁸³ calls attention to the association of oxaluria with *Taenia* infestation and suggests that the source of the oxalate is the metabolism of the parasite within the intestine. He and Tonnet¹⁵¹ report on *in vitro* experiments that demonstrate that, during the metabolism of *Taenia*, glucose and oxalic acid are formed at the expense of glycogen. Finck¹⁴⁹ reviews the literature and reports 58 cases of oxaluria in which parasitic infestation was present as follows: 7 cases with *Lambia*, 2 with *Taenia* and 49 with

caris He reports that examination of the stools of these patients showed, in addition to the evidence of parasitic infestation, large numbers of calcium oxalate crystals and an increase in undigested starch granules He postulates that the parasites interfere with the normal functioning of the pancreas and thereby indirectly affect oxalic acid metabolism He states that the successful elimination of the parasites was accompanied by disappearance of oxaluria Buche¹⁵² comments on the frequent association of colon-bacillus bacteriuria and oxaluria McCinnin and Lombardi^{153 154} isolated a strain of colon bacillus that produced oxalic acid in vitro and caused oxaluria when administered in capsules to healthy subjects

A third source of blood and urinary oxalate is the intermediary metabolism of tissues This is by far the most controversial and confusing of all the aspects of the subject In view of the questionable reliability of the methods used and the doubtful accuracy of many of the reported experiments, it is impossible to evaluate the status of the problem on the basis for the concept of endogenous production of oxalate lies in the demonstration that animals and human beings maintained on supposedly oxalate-free diets or undergoing starvation experiments continue to excrete oxalic acid in the urine This finding has been verified by a number of observers—Herkel and Koch¹⁵² in rabbits, Borgström¹⁵⁵ in guinea pigs, Jürgens and Spehr¹⁵⁶ in dogs, Adolph and Liang¹⁵⁶ in rats and Herkel and Koch¹⁵² and Jürgens and Spehr¹⁵⁶ in man It has been suggested that oxalic acid is related in some mysterious manner to the metabolism of carbohydrate This originally arose from the fact that in vitro oxalic acid is produced by the action of nitric acid on glucose—hence the name "sugar acid" Loeper¹⁵⁵ considers tissue carbohydrate, especially glycogen, to be a potent source of oxalic acid He and his co-workers¹⁵⁶ report that experiments on slices from rabbit's liver and heart show that, as the tissue glycogen decreases, the glucose and oxalic acid increase In addition, Loeper¹⁵⁵ claims that the coexistence of hyperglycemia and hyperoxalemia in diabetic patients and the simultaneous response of each to insulin support the concept of a specific interrelation The previously mentioned experiments of Herkel and Koch and of Jürgens and Spehr tend to substantiate this idea Oikawa¹⁵⁷ reports an extensive literature showing that hyperglycemia induced by the injection of glucose or adrenalin is accompanied by hyperoxalemia and often by oxaluria His own experiments, although purporting to substantiate those of other observers, fail to show a significant effect of either glucose or adrenalin

In addition to the investigations on the interrelation of carbohydrates and oxalic acid metabolism, a variety of other substances have been studied Most of the work has been directed toward the discovery of oxalate precursors by means of the

determination of blood and urine oxalate after the administration of test substances Glucose,¹⁵⁴ aspartic acid,¹⁵⁴ asparagine,¹⁵⁴ ethylene glycol,¹⁵⁵ ethylene monoacetate,¹⁵⁸ glycine,¹⁵⁹ creatinine,¹⁵⁹ purines,¹⁵⁹ glyoxal¹²² and glycolic acid¹²² have been reported as leading to an increase in oxalic acid A decrease in oxalate is said to follow the administration of pyruvic acid¹⁵⁴ Glycine,¹⁵⁴ alanine,¹⁵⁴ glutamic acid,¹⁵⁴ butyric acid,¹⁵⁴ fructose¹²² and oxamide¹²² have been ineffective

Some evidence has accumulated that implicates purine and pyrimidine metabolism in the production of oxalic acid Rodillon⁷⁷ suggested a schema in which oxalic acid appeared as an end product of a series of reactions beginning with uric acid and progressing through alloxan, oxaluric acid and finally urea and oxalic acid It is perhaps of interest to note that alloxan, now widely used in the experimental production of diabetes, is a ureide of mesoxalic acid

In this country some support for the interrelation of pyrimidine and oxalic acid metabolism has been obtained from the work of Cerecedo and his associates¹⁵⁹⁻¹⁶² They fed to dogs various substances considered as possible intermediaries in pyrimidine metabolism and then measured the urea and the oxalic acid content of the urine Although aware of the inadequacy of the methods for the determination of oxalic acid, they concluded that their results had relative, if not absolute, significance Uracil, oxaluric acid, formyloxaluric acid, isobarbituric acid and isodialuric acid resulted in an elevation of urinary urea, and oxaluric acid also caused a rise in urinary oxalic acid In addition, parabanic acid caused an elevation of urinary oxalate but along with alloxan and alloxantin did not appear to be involved in the metabolism of uric acid As a result of these investigations, the authors suggested a schema beginning with uracil and progressing through isobarbituric acid, isodialuric acid and oxaluric acid to the end products, urea and oxalic acid This is an interesting series of experiments that apparently have been neither confirmed nor disproved It is interesting to speculate whether such a substance as thiouracil could give rise to oxalic acid

It is probably worth mentioning at this point that in the citric acid cycle postulated for the oxidative breakdown of pyruvate, a schema in which vitamin B is intimately involved, a number of dicarboxylic acids have been implicated¹⁶³ Thus, citric, α -ketoglutaric, succinic, fumaric, malic and oxalacetic acids have important places in the cycle The structural relation of oxalacetic and oxalic acid might give rise to speculations concerning a possible physiologic relation At the present time, however, there is no available evidence that oxalic acid is concerned in the intermediary metabolism of the citric acid cycle or is connected in any manner with the formation or breakdown of oxalacetic acid in cellular metabolism

Blood oxalate levels are reported as elevated under the influence of adrenalin,^{167, 164} thyroxine¹⁶⁴ and anoxemia¹⁶⁶. The administration of insulin^{58, 145, 164} and thyroidectomy,¹⁶⁴ on the other hand, cause a fall. Urinary oxalate is elevated on exposure to hydrocyanic acid¹⁶⁶ and after exercise.¹⁶⁷ Dinitrophenol¹⁶⁶ and quinine¹⁶⁶ cause a fall in urinary oxalate.

Fate of Oxalates

The confusion centered around this aspect of the subject is enormous, and will not be clarified until a satisfactory method for the accurate determination of small quantities has been developed. The perplexity of the problem at the present time can best be demonstrated by enumerating some of the theories^{132, 136, 143, 155, 156, 168-170} that have been suggested. Oxalic acid is oxidized in the body, it is resistant to further breakdown, all organs are able to metabolize oxalic acid, blood forms and decomposes oxalic acid, skeletal muscle oxidizes oxalic acid but liver does not, oxalic acid is formed in the liver and skeletal muscle, liver cells destroy it, liver cells excrete it into the bile, oxalic acid is a source of carbon monoxide in the body, it is formed at the expense of uric acid, it is transformed into carbonate, it is changed into formic acid, and it is formed under conditions of reduced tissue metabolism.

There is no doubt that oxalates are excreted by the gastrointestinal tract and the kidney and appear in the urine, and there is some evidence that they also may be excreted in the bile. Their persistence in the urine during starvation suggests that to a certain extent they are endogenous in origin, but this problem as well as that of their subsequent fate requires further investigation.

ANTICOAGULANT ACTIVITY OF OXALIC ACID AND CERTAIN PLANT EXTRACTS

In 1939, Steinberg and Brown¹⁸⁶ reported briefly that extracts of certain plants decreased the coagulation time of rabbit's blood. Among the potent sources of these extracts were shepherd's purse, wood sorrel, beets, oxalis, citrus fruits, rhubarb and euphorbia. Attempts to determine the active principle resulted in the isolation of a colorless, crystalline material that they identified as oxalic acid. Of the various extracts, that from shepherd's purse apparently is best known. Copley and Lalich¹⁷¹ state that it is a common North American and European weed that in the past was used internally, as well as locally, to control hemorrhage. The report that oxalic acid administered parenterally accelerated coagulation of blood was rather startling in view of its well known anticoagulant activity *in vitro*. Nevertheless, it was used in the treatment of a large number of patients with a variety of hemorrhagic tendencies, as well as prophylactically to prevent postoperative bleeding. Steinberg et al.¹²⁸

reported more fully on their work in 1940 and concluded that the normal blood oxalate values range between 5.0 and 7.5 mg per 100 cc., that the coagulation time of blood varies inversely with its oxalic acid content, that the intravenous administration of oxalic acid causes a rise in blood oxalate greater than can be accounted for by the quantity of oxalate injected, that the intravenous injection of oxalic acid causes a decrease in coagulation time and that the administration of parenteral oxalic acid to several thousand patients with various types of hemorrhage gave a high incidence of gratifying results. It is important to note that their oxalate determinations were made by a modification of Suzuki's method, a procedure recently criticized by Barrett¹³⁰ and that their coagulation times were determined by the capillary-tube method, which is of questionable reliability.

Schumann¹⁷² reported the use of Koagamin, of which the active principles are oxalic and malonic acid, in a variety of obstetric and gynecologic hemorrhagic episodes with satisfactory clinical results, but his published studies are inadequate and the results are not convincing. Milliken,¹⁷³ in the same year, reported the successful use of Koagamin in the prevention of postoperative hemorrhage in prostatic surgery. He stated that the coagulation time was reduced by half, but failed to note the method used and gave no protocols. Martin¹⁷⁴ reported that intravenous oxalic acid reduced the clotting time of vitamin K-deficient chicks almost to normal and decreased the prothrombin time. In rabbits, he found that doses between 0.5 and 30.0 mg per kilogram of body weight caused a reduction in clotting time, whereas toxic doses of 100 mg per kilogram caused a prolongation. The clotting time in heparinized rabbits was unaffected. Page,¹⁷⁵ using the Lee-White method for the determination of clotting time, reported transient reductions to the upper limits of normal in three hemophiliacs after the intravenous injection of oxalic acid. One patient, however, failed to respond to a second administration. Blain and Campbell¹⁷⁶ reported experiments on rabbits and on 440 operative cases involving a wide variety of surgical procedures and claimed that the clinical results were excellent. Likewise, Herbst and Weinstein,¹⁷⁷ using Koagamin on 15 normal cases and 12 operative cases, concluded that a significant decrease occurred in bleeding time and coagulation time. The methods used (Duke method and capillary-tube method), however, are not the most reliable ones. Hulse¹⁷⁸ discussed the subject briefly, stated that oxalic acid definitely decreased blood clotting time and increased blood viscosity and was antagonistic to heparin and hirudin and recommended its use clinically. He presented no laboratory verification for his statements. A number of investigations that fail to confirm the value of oxalic acid, although quite limited, appear to warrant attention. Foster,¹⁷⁹ employ-

ing doses of oxalic acid comparable to those suggested for clinical use, was unable, employing a modification of the Howell method, to demonstrate any effect on the clotting time in normal rabbits, heparinized rabbits or vitamin K-deficient chicks. With large doses in rabbits he obtained a great prolongation of clotting time. Johnson,¹⁸⁰ using both oxalic acid and Koagamin, obtained no effects whatsoever on the coagulation time of 5 hemophiliacs. Copley and Lalich¹⁷¹ studied 2 cases of hemophilia with respect to bleeding time, clotting time and clot resistance after combined treatment with blood transfusions and an extract of shepherd's purse. All the bleeding times were normal. The clotting was decreased on one occasion only, and this followed the administration of both blood and extract. Clot resistance tended to be increased with the combined therapy. They raised the question of a phytothrombin in certain plant extracts.

In view of the fact that Koagamin is available for use, it is regrettable that most of the published experiments are based on the use of hematologic methods that are not the most reliable ones. At the present time it must be concluded that the use of oxalic acid or other dicarboxylic acids or plant extracts rich in oxalates for the treatment of bleeding disease is controversial, and that its exact value as a therapeutic measure requires further study.

NEW HAMPSHIRE MEDICAL SOCIETY

PROCEEDINGS OF THE ONE HUNDRED AND FIFTY-FOURTH ANNIVERSARY

House of Delegates, May 14 and 15, 1945

THE House of Delegates convened at the Hotel Carpenter, Manchester, on May 14, 1945, at 7 30 p m, with Speaker Ralph W Tuttle presiding. The following members answered the roll call

The President, *ex-officio*
 The Secretary-Treasurer, *ex-officio*
 Richard W Robinson, Laconia
 Francis J C Dube, Center Ossipee
 W J Paul Dye, Wolfeboro
 Walter H Lacey, Keene
 Walter F Taylor, Keene
 Arthur B Sharples, Groveton
 Ralph N Jones, Whitefield
 Leslie K Sycamore, Hanover
 Howard N Kingsford, Hanover
 Israel A Dinerman, Canaan
 George F Dwinell, Manchester
 Donald M Clark, Peterborough
 Sullman G Davis, Nashua
 Robert E Biron, Manchester
 Mildred Chamberlin, Concord
 William P Clough, Jr, New London
 Gerard Gaudreault, Concord
 Willard C Montgomery, Epping
 Harry B Carpenter, Portsmouth
 Robert W Tower, Plaistow
 George G McGregor, Durham
 Francis H Nolin (alternate for Donald C Moriarty, Newport)
 B Read Lewin, Claremont

The Speaker declared a quorum present. On motion duly made and seconded, it was voted to omit the reading of the previous minutes, because of the publication of the proceedings.

The Speaker appointed the Credentials Committee as follows: Drs Clough, Jr, Biron and Dube

To the Committee on Officers' Reports, he appointed Drs Robinson, Chamberlin and Lewin. To the Committee on Communications and Memorials, he appointed Drs Davis, Handy and Dinerman. To the Committee on Nominations, he appointed Drs Clark, Dye, Tower, Moriarty and Sharples. For the Committee on Credentials, Dr Clough, Jr, reported that the credentials were in order.

The Secretary-Treasurer, Dr Carleton R Metcalf, presented his report, as follows:

MEMBERSHIP, DECEMBER 31, 1944

PAID	
Belknap County	26
Carroll County	13
Cheshire County	21
Coos County	25
Grafton County	57
Hillsborough County	98
Merrimack County	54

The total membership on December 31, 1944, was 546. This is an increase of eleven over the preceding year. Louis W. Flanders of Dover, who was elected president of the Society in June, 1924, has recently died. Frederic P. Scribner, of Manchester, for many years a valuable member

of the Committee on Scientific Work, died on July 17, 1944.

At the request of the Trustees, the Benevolence Fund has been turned over to that body. For several years heretofore, while the Trustees have been the official custodians, the accumulation of this fund had been entrusted to the Secretary-Treasurer. In last year's report I stated "This fund is to accumulate until it reaches \$10,000. The interest from the fund may then be used to help needy members of the Society." This statement was incorrect, there are several hundred dollars in the Benevolence Fund that are now available. I misinterpreted Chapter 11, Section 3, of our by-laws, which reads as follows:

When the total sum of the Benevolence Fund reaches ten thousand dollars (\$10,000) the House of Delegates may increase or decrease the yearly allotment from the dues of each member to the fund, and it shall also decide whether the income from the general fund shall continue as a source of revenue to the Benevolence Fund.

It should be noted that the allotment from the dues may be changed when the total sum reaches \$10,000. This statement implies, I suppose, that the allotment may not be changed before that time. As a matter of fact, two changes have been made, although the total sum has not yet been reached. A few years ago the amount of the annual assessment was doubled, and last year the House of Delegates voted to discontinue for one year further contributions to this fund from the annual dues. Such a vote was apparently not valid.

The proper course a year ago would have been to propose an amendment to this section of the by-laws at the first session of the House of Delegates and to vote on it at the second session, but if the intention of the House of Delegates has not been properly carried out and the customary contribution is made to the Benevolence Fund for the past year, it will merely mean robbing Peter to pay Paul, for we shall have to transfer money from the General Fund to the Benevolence Fund.

I suggest that Chapter 11, Section 3, be referred to the Committee on Amendments to the Constitution and By-laws, with the recommendation that it be modified or eliminated. If a change is voted it might be possible to make it retroactive for one year, so that the intention of the House of Delegates a year ago may be carried out. We must also decide about an assessment for the coming year.

While no money was added to the Benevolence Fund from the annual dues last year, we did receive donations from the following auxiliaries:

Hillsborough	\$18 75
Merrimack	20 00
Strafford	48 50

A bond received from the State Auxiliary in 1943 was cashed, and the further sum of \$74 00 was added to the fund in 1944.

In accordance with your instructions, \$50 00 was given to the Cancer Committee for its work.

I asked each county society to have its members contribute \$1 00 apiece to the National Physicians' Committee. During 1944, \$191 00 was received from the several counties, as follows:

Belknap	\$25 00
Coos	25 00
Merrimack	50 00
Rockingham	48 00
Sullivan	14 00
Strafford	29 00

In addition, the Hillsborough County Medical Society contributed \$51 00, which was sent directly to the National Physicians' Committee.

A report on the New Hampshire Physician Service, or Blue Shield, which was inaugurated and sponsored by the House of Delegates, will be given by its president, Leslie K. Svacumore. A further report will be given by the Executive Secretary at the general meeting.

There has been no vital legislation in the General Court during its recent session. I was on hand at five or six committee meetings, usually as an onlooker but, at the request of the State Board of Health, I spoke briefly on three occa-

sions as an individual, not as a representative of the New Hampshire Medical Society. The bills that were under discussion were

A bill to transfer certain health work now done by the Labor Department to the Department on Public Health. The bill was approved by the Committee on Public Health of the Society.

A bill to eliminate the doctor of medicine from the Board of Optometry, thereby placing five optometrists on the board instead of four optometrists and a physician.

A bill to liberalize the use and the coloring of oleomargarine.

A bill to enrich flour and bread by the addition of the vitamins that are initially removed in the process of milling.

A bill to require that employees of restaurants and other eating places obtain a medical certificate annually stating that they are free from tuberculosis and venereal diseases.

An increased fee is now being allotted to physicians for the obstetric care of the wives of servicemen. Beginning September 28, 1944, this fee was raised to \$50.00.

During the past year or two I have heard a statement made several times that the Society was being run by the "Old Guard." There is considerable truth in this statement, and I suggest that the Committee on Nominations scan the committee lists this year. While it may be desirable, because of their experience, to have members of the "Old Guard" in some of the key positions, it is likewise desirable to give younger men committee appointments so that they themselves will be familiar with the work of the Society when, a few years from now, they themselves become elder statesmen.

Of course, a good many of our younger men are in the armed services, but if it seems desirable, the Committee on Nominations ought to be able to make a start in the direction that I have suggested.

A modified Wagner Bill is in the making at Washington. I am told that it is the same old bill, the leopard has not changed his spots. Our two senators and our two congressmen are opposed to it. So far as I can find out, the doctors in the armed services are generally opposed to it and are fearful that something may be put over on them while they are absent.

Another group of planners in Washington is working out a new proposal for government-sponsored medical care.

The post-war project is being drafted by the United States Public Health Service and the Department of Agriculture's Postwar Planning Committee. It would spur a hospital building program such as the Nation has never seen. It would send thousands of doctors, dentists and nurses into rural areas and other places with little service, and it would provide compulsory health insurance.

The sponsors of the plan contend that there are many untended sick people in this country. They claim that in one third of the Nation's counties there is no hospital of any type and that thirty-three rural counties had no doctors at all even before physicians were called into the armed forces. They claim that another two hundred and forty-one counties had only one doctor for every two thousand people. The planners claim that the trouble is economic—that doctors go where there are concentrations of high-fee patients, and that the only solution is for the Government to step in.

Surgeon General Thomas Parran, head of the Public Health Service, declares, "The financing of a program for the total health care of the population must come through some system of prepayment, probably on an insurance basis, through public taxes or, perhaps, through a combination of both." Applied to the Nation, estimates indicate the cash involved each year in such a compulsory health scheme would be about \$1,800,000,000. A doctor operating under this federal plan would be given his choice of three different methods of obtaining his income.

In addition to this health program, the plan calls for special new centers to administer and practice public health. Each metropolitan area would have one or more base hospitals, from which there would radiate a series of rural hospitals more limited in service. There is also planned a program of health centers, which would be field stations of the future system of public health and medical care. Mobile clinics are also proposed.

Senate Bill 191 is much more modest. It provides for hospitals and health centers under state supervision but does

not regiment the doctors. This bill is sponsored by the American Hospital Association.

What are the members of the Society going to do if the Wagner Bill or some similar bill becomes law? Are we going to refuse to sign on the dotted line and try to practice medicine as we have heretofore practiced it, or are we going to become government doctors? Are we going to exhibit inertia, which is sometimes a property of mind as well as of matter?

We ought, individually, to give thought to this matter now. We ought to realize that changes in the method of practice are bound to come and that we ought to have a constructive hand in shaping such changes. We ought to take time by the forelock. Probably the best course is to accept wholeheartedly the leadership of the American Medical Association. We ought, at any rate, to hang together, for, as a wise old philosopher once said, "We must all hang together, or assuredly we shall all hang separately."

The Secretary-Treasurer then presented a letter from Elmer V. Andrews, Commissioner of the Department of Public Welfare, reading as follows:

At the spring meeting of the Medical Advisory Committee of Ophthalmologists, which was held May 2, 1945, at the Eagle Hotel, Concord, the committee voted to invite Thomas F. Reid, M.D., of Dover, to become a member of this committee.

In order that the records may be kept up to date and the Society may be kept informed on all departmental matters relating to the medical care field, I am writing to request that the House of Delegates approve Dr. Reid's acceptance of an appointment to this committee.

Dr. Metcalf explained that Dr. Reid was to meet with this committee three or four times a year, and consult with them as to the care of the eyes. In this way, the Society would be giving its sanction for the ophthalmologists on the committee. He requested that the Speaker entertain a motion to approve Dr. Reid's appointment. Such a motion was made by Dr. Dye, and was duly seconded and was carried.

Dr. Metcalf then outlined a letter from Helen Hinman, nutrition consultant in the State Board of Health. She wished to have a committee to help her in the nutrition of the children of the State. She had selected three men, who had agreed to serve in an advisory capacity. These men were Drs. Colin C. Stewart, of Hanover, Brockway D. Roberts, of Durham (chairman), and Simon Stone, of Manchester. On Dr. Metcalf's suggestion, it was moved and seconded that they be appointed as a Committee on Consultation in Nutrition.

Dr. Robinson, speaking on the motion, said that although he had no objection to the appointment, he objected to the precedent it would establish of permitting persons outside the Society to dictate or determine one of its committees. Dr. Metcalf replied that he had dictated the committee to a certain extent, since he had asked Miss Hinman to give him the names of the men she wanted, promising to submit them to the House of Delegates. She apparently wanted to have people who were familiar with nutrition, were interested in it, and would be willing to serve. Dr. Robinson then withdrew his objection, and the motion was duly carried.

Dr Metcalf next presented a financial report from Trustees for January 1, 1943, to December 31, 1944, as follows

Total	\$6,239 81

Dr Robinson moved the acceptance of this report, and the motion was duly seconded and was carried

Dr Robinson for the Committee on Officers' Reports then spoke as follows

This Committee believes that it voices the general opinion of the members of our society in expressing respect for the diligent efforts and gratification for the accomplishments of the Secretary-Treasurer. We note with sorrow the deaths of two former officers of this society. We move the approval of this portion of our report

This motion was duly seconded and was carried

Dr Robinson then spoke as follows

Regarding the predicament that has arisen from alterations in the allocation of dues to the Benevolence Fund, we suggest that the Benevolence Fund return to the General Fund the amount it has received in excess of that designated in the by-laws after deducting the amount of the assessment that it should have received last year, had not such assessment been illegally withheld. We likewise suggest that the by-laws be amended to permit suspension of such assessments by unanimous vote of the House of Delegates at a regular meeting for the period of one year. To accomplish this, we move that Chapter XI, Section 3, of the by-laws be amended to read as follows

When the total sum of the Benevolence Fund reaches ten thousand dollars (\$10,000), the House of Delegates may increase or decrease the yearly allotment from the dues of each member to the fund, and it shall also decide whether the income from the General Fund shall continue as a source of revenue to the Benevolence Fund, except that at the time of any regular meeting of the House of Delegates, the yearly allotment may be abolished, increased or reduced, for a period of one year only, by unanimous vote of the members assembled

We move the adoption of this portion of our report, and that the proposed amendment to the by-laws be turned over to the Committee on Amendments to the Constitution and By-laws

The reason we make the suggestion that the Benevolence Fund return to the General Fund the amount it has received and take out money that should have been assessed last year is that we see no way of taking retroactive care of the fund

The Speaker asked whether this proposal should not be made on Amendments to the Constitution and By-laws. Dr Robinson said that it had been recommended to that committee

Dr Wilkins said that the original purpose was to build up a fund of \$10,000. The fund was started in 1932, and since there was at one time plenty of money, the rate was increased from 50 cents per member to \$1.00. Last year, the assessment was entirely suspended, because of the decrease of funds due to members' being in the Service. He added that he had no objection to the proposed amendment, but that it would simply slow up the reaching of the final goal

Dr Robinson expressed his willingness to yield any proposal to the Committee on Amendments to the Constitution and By-laws, but said he did not believe that a by-law could be abolished or suspended and then legalized a year later. He added that the by-law must be changed as of a particular time, and that it could not be changed as of last year now

Dr Kingsford thought that the Trustees intended the Benevolence Fund to be allowed to reach \$10,000, and then to be used in whatever way the House of Delegates desired. As he understood it, if the new motion went through, money could occasionally be taken out of the fund before it got to be \$10,000

Dr Dye asked whether the General Fund would have been faced with a deficit if the assessment had not been suspended last year. Dr Metcalf answered in the affirmative

Dr Dube suggested simply increasing the dues Dr Robinson then spoke as follows

As I understand it, several years ago, contrary to the by-laws, an allotment to the Benevolence Fund was increased. Last year, it was voted not to allocate the fund at all. Whatever is done must take care of the two circumstances. The best procedure, it seems to me, is to devise a simple arrangement of bookkeeping that requires no amendment, and to pass a simple amendment permitting the House of Delegates, by unanimous vote, to set the assessment aside for one year. This could be repeated as often as desired, and increased or decreased on the same basis. It is easy to refer this matter to the Committee on Amendments to the Constitution and By-laws, but it does not take care of the past changes and allocations.

The speaker pointed out that the by-laws could not be changed at one session and that any amendment proposed would have to be laid on the table until the following morning's meeting. He then put the original motion to vote, and it was carried.

Dr Robinson for the Committee on Officers' Reports said that it approved the policy of transfusing the offices and committees with new and younger blood, so that more of the members would be able to derive the benefits of service performed to the Society. It did not believe that new blood, properly typed, was so apt to cause reactions as would repeated usage of blood from the same donors. He moved the acceptance of this portion of the report, and the motion was duly seconded and was carried.

Dr Robinson then spoke on the questions propounded in the Secretary's report respecting individual attitudes to proposed federal legislation concerning the distribution of medical care. He said that various aspects of this subject had been touched on in the report of the delegate to the American Medical Association and in the report of the Committee on Medical Economics. It was the committee's best judgment that physicians should make up their minds that they will have no part in any plan that in one iota reduces the freedom of American medicine, but should hold themselves ready to co-operate constructively toward possible plans of the future that may promise better distribution of adequate medical care, provided they can be freed of this and other important evils. As Dr Metcalf had said, the Society could do no better than to follow the lead of the American Medical Association in these matters. He moved the acceptance of this portion of the report, and the motion was duly seconded and carried.

Dr Lawrence then spoke as follows

The House of Delegates of the American Medical Association is made up exactly like the Society's House of Delegates. The delegates to the former come from the various states, and those to the latter from the counties. After all, the county is the autonomous body, and not the American Medical Association or the state association. So that ideas of this kind, with regard to program or planning, can really best originate in the autonomous body and can be passed on from there. Inasmuch as we, as autonomous bodies,

are represented by delegates elected by them, those delegates should be instructed. In other words, it is one thing to say that we take the leadership of an organization that we think is, in a sense, other than ourselves, and another thing to take a leadership in which we take an active part in regard to the future of medicine at the present time. It seems to me that the future is best going to be served when every one of us takes his part in planning for the future and not asking someone to do it for him.

Dr Dye then presented the following report.

Report of the Committee on Amendments to the Constitution and By-laws

The majority of so-called "affiliate" members of the New Hampshire Medical Society are those physicians who have been members of this society for a continuous term of fifteen years and are either not less than sixty-five years of age or totally disabled, and who have been given such membership classification at the request of their county societies by a majority vote of the House of Delegates. Largely for this reason, many physicians throughout the State and the Merrimac County Medical Society, by direct unanimous vote, have suggested that the term "affiliate" shall be changed to the term "life," throughout the constitution and by-laws. This committee therefore recommends that the following changes be made in the constitution and by-laws:

The Constitution

Article 4, Section 1 This society shall consist of members, life members and honorary members.

Article 4, Section 3 Life members shall be those members whose dues are remitted.

The By-laws

Chapter 1, Section 5 Any physician who has been a member of this society for a continuous term of fifteen years, and is either not less than sixty-five years of age or totally disabled, on the request of his county society may be made a life member on a majority vote of the House of Delegates. Life members shall have the same rights and privileges as other members of the Society, but shall not be required to pay dues.

Chapter 3, Section 1 The general meetings shall include all registered members, life members, honorary members and guests, who shall have equal rights to participate in the proceedings and discussions, and, except guests and honorary members, to vote on pending questions. Each general meeting shall be presided over by the president, or in his absence or disability, or by his request, by the vice-president. Before it, at such time and place as may have been arranged, shall be delivered the annual address of the president and the annual oration, and the entire time of the session so far as may be shall be devoted to papers and discussions relating to scientific medicine.

W J PAUL DYE, Chairman
FREDERICK S GRAY
RALPH N JONES

Dr Robinson said that the Committee on Officers' Reports approved the changes as outlined in the report of the committee, and moved that the constitution and by-laws be so altered, subject to constitutional procedure. The Speaker directed that the matter be postponed until the morning meeting.

Dr Amsden then presented the following report

Report of the Necrologist

NAME	ADDRESS	DATE OF DEATH
Bergeron, Pierre	Manchester	May 7, 1944
Flanders, Louis W	Dover	January 16, 1945
Grimes, Warren P	Hillsborough	November 13, 1944

awkins, Frederick L	Meredith	November 8, 1944
ndman, Elbert A	Plaistow	October 18, 1944
rmandin, Armand	Laconia	February 14, 1945
er, Charles F	Manchester	January 29, 1945
rgent, Frank H	Pittsfield	July 11, 1944
nbner, Frederick P	Manchester	July 17, 1944

HENRY H AMSDEN, *Necrologist*

Dr Robinson for the Committee on Officers' reports recommends the acceptance of this report, and in recognition of the service given by the departed members to the Society, suggested that the House rise and honor their names with a minute of silence. This was done.

Dr Stewart then presented the following report

Report of the Committee on Child Health

War conditions have again precluded much activity on the part of this committee. We expect shortly to send out a letter summarizing the most recent views on prophylaxis against the infectious diseases of childhood. This would include the use of gamma globulin as protection against measles, this material having recently become available through the State Department of Health.

Safeguarding the health of children in foster homes is another subject that has been considered. Protection against possible exposure to tuberculosis, along the lines discussed with Dr Kerr, has been urged.

We have reviewed adoption practices in New Hampshire. Many doctors do not know the aids available to them in this field, and we have co-operated with the Children's Aid Society in the preparation of literature designed to bring this information to them. Your chairman appeared at a legislative hearing relative to proposed changes in the law concerning adoption.

COLIN C STEWART, *Chairman*
B READ LEWIN
FRANKLIN ROGERS

Dr Robinson for the Committee on Officers' Reports approved the report and moved its acceptance. The motion was duly seconded and carried.

Dr Wilkins then presented the following report

Report of the Committee on the Control of Cancer

Two years ago the State Executive Committee of the Field Army of the American Cancer Society offered financial aid to physicians connected with the state cancer clinics for refresher courses at various cancer centers in New York City and Boston. Only six physicians have availed themselves of this privilege, but each of these has expressed deep appreciation of the clinical privileges afforded him in these centers. It is now suggested that plans be made during the coming year for one or two days' intensive instruction in the diagnosis and treatment of cancer, the course to be open to general practitioners as well as to those especially interested in cancer treatment. These plans will be elaborated further and communications regarding them will be sent to every member of the Society. It is anticipated that the expenses of attending this course will be borne by the Field Army of the American Cancer Society. The Executive Committee of the Field Army would like the approval of this society for this plan.

The Field Army has conducted its usual drive for members during April, and it is to be noted that the change in name from "Women's Field Army" to "Field Army" was made in order to encourage the enlistment of men as well as women interested in cancer control. The Field Army has continued its program of lay education and preparation of dressings for indigent cancer patients, and has provided transportation for patients to clinics and hospitals. This year educational material for cancer educa-

tion has been furnished the high-school science classes in both public and parochial schools in Manchester, and it is to be hoped that such instruction will be introduced into the high schools of all communities in the State.

The New Hampshire Cancer Commission clinics have functioned as usual. The total number of visits to the clinics was 1582. Of these, 705 were made by new patients and 877 were return visits. Of the new patients, 61 per cent had cancer, this percentage having gradually risen from 36 per cent in 1934. During the last fiscal year the Commission paid for 4338 hospital days for patients unable to finance their own hospital expenses. In comparison with most other states, New Hampshire is fortunate in the facilities for cancer diagnosis and treatment made available by the Cancer Commission.

Your committee has sent three communications to all physicians within the State. The first was a pamphlet containing two articles, "The Doctor's Responsibility" and "The Office Detection of Cancer." Under both these subjects were discussed points that had been stressed before in previous letters, all of them important in relation to cancer diagnosis. The second was a letter explaining the difference between carcinoma simplex and adenocarcinoma, about which there had been confusion in the minds of some physicians after receiving pathological reports of tumors or biopsies. It stated that carcinoma simplex is usually more malignant and more invasive than adenocarcinoma and metastasizes more rapidly. The third was a letter reiterating the need of not overlooking the importance of any abnormal rectal or vaginal bleeding, the necessity of recognizing the fact that such bleeding is usually due to pathologic change and the need for investigation until the cause is discovered. Mention was also made that after the menopause, estrogenic therapy may cause flowing similar to that resulting from adenocarcinoma of the fundus. In rectal bleeding, physicians were reminded again of the proper sequence of methods to determine the cause, in the order named: digital examination, proctoscopy and x-ray examination — not the reverse.

Of the \$50.00 appropriated for the use of the committee, there was spent \$31.20 for stationery, postage and printing. A check for the balance of \$18.80 has been sent to the Treasurer, the large balance being due to fewer physicians on the mailing list. The committee requests \$40.00 for the ensuing year.

GEORGE C WILKINS, *Chairman*
RALPH E MILLER
GEORGE F DWINELL, *Secretary*

Dr Robinson for the Committee on Officers' Reports commended highly the diligent efforts of the Committee on the Control of Cancer, and said that the Committee was confident of a continuation of the same effort in the future. He recommended that the request for \$40.00 to carry on its activities be granted. The committee, he continued, took recognition of the fact that early diagnosis is the best present answer to a lower mortality from this disease, and wished to go on record as approving the suggested plan for intensive instruction in the diagnosis and treatment of cancer as outlined in the report. He moved its approval, and also moved that the State Executive Committee of the Field Army of the American Cancer Society be given notice of such action on the part of the House of Delegates. This motion was duly seconded and carried.

Dr Blood then presented the following report

Report of the Committee on Maternity and Infancy

This is the eleventh year of this study of maternal and infant deaths.

Maternal Mortality

There were 26 maternal deaths and 8695 live births, a maternal mortality rate of 2.99 per 1000 live births. This may be compared with the figures for 1943 of 24 maternal deaths and 9825 live births, a maternal mortality rate of 2.44 per 1000 live births. Over a period of ten years, the highest mortality was that of 1935, 6.1 per 1000 live births, with 45 deaths, the lowest was that of 1942, 1.6, with 15 deaths.

The 26 maternal deaths have been classified according to the *International List of Causes of Death*, as follows:

CLASSIFICATION	No of DEATHS
Puerperal toxemia (death after delivery)	9
Infection during childbirth and puerperium	7
Accidents of pregnancy (death before delivery) *	5
Inversion of uterus	2
Hemorrhage (1 before delivery and 1 after)	2
Ectopic gestation	1
Total	26

The committee has reclassified these for the purpose of this report in the following way:

CAUSE OF DEATH	
Accidents of pregnancy	11
Puerperal emboli	4
Anesthesia	2
Inversion of uterus (with hemorrhage)	2
Attempted abortion with poison	1
Cerebral embolus (before delivery, cause unknown)	1
Multiple pulmonary emboli due to meconium and amniotic fluid (before delivery)	1
Hemorrhage	2
Internal hemorrhage	1
Probable placenta previa (case seen only by coroner)	1
Toxemia (all types)	9
Puerperal sepsis	3
Ruptured ectopic pregnancy	1
Total	26

The committee has further classified these cases on the basis of data submitted in one of three groups: unavoidable, patient's fault and probably avoidable. There were reports on 5 deaths that gave insufficient data for classification. In 2 of these, one eclampsia and the other puerperal infection, no information was submitted. The other 3 deaths were recorded on the certificate as due to postpartum eclampsia, eclampsia and internal hemorrhage, respectively. The remaining 21 cases were classified as follows: unavoidable, 11; patient's fault, 6; avoidable, 4. Of the 11 deaths classified as unavoidable, 6 were due to embolism, 2 to inversion of the uterus, 2 to toxemia and 1 to ectopic gestation. Of the 6 deaths classified as the patient's fault, — that is, she failed to seek medical attention or failed to carry out medical advice, — 3 were due to toxemia and 1 to hemorrhage, probably placenta previa, in 1 case the actual cause of death was pneumonia following a normal delivery when the patient left the hospital against advice, and in 1 case death was due to poison from drinking oil of cedar in an attempt to abort. Of the 4 deaths classified as probably avoidable, 2 were due to anesthesia. The committee is of the opinion that, with the difficulty at the present in securing physicians to give anesthesia, the attending physician must assume the responsibility for it and be more careful and attentive to the procedure. There was 1 death due to toxemia that the committee thought might have been avoided had adequate treatment been given. One patient died of postoperative complications following a cesarean section. In this case some of the committee believed that the procedure of choice would have been to allow the patient to deliver normally.

All the deliveries took place in a hospital.

The deaths by county were as follows: Belknap, 1; Carroll, 1; Cheshire, 1; Grafton, 2; Hillsborough, 8; Merrimack, 2; Rockingham, 3; Strafford, 6; and Sullivan, 1. Coos County is the only one having no maternal deaths.

The committee has certain recommendations to make and these will appear later in detail in a printed report, copies of which will be sent to each member. Briefly the points are as follows:

The value of Rh-factor typing in obstetric patients and having facilities available for typing in hospital laboratories.

The value of autopsies, with an increasing effort on the part of physicians to obtain an autopsy.

The increased responsibility of the attending physician in giving patients in labor an anesthetic.

The treatment in toxemias. (There is evidence that physicians still fail to give adequate and proper treatment in toxemias. Toxemia is still highest on the list as a cause of maternal deaths. The treatment in toxemias cannot be overstressed.)

Infant Mortality

Included in this group are those infants who died under one year of age. There were 322 infant deaths in 1944, giving an infant death rate of 37.0 per 1000 live births, as compared with 420 deaths in 1943, a rate of 42.9. Prematurity as a single cause still accounts for the largest number of deaths.

Stillbirths

There were 232 stillbirths in 1944, as compared with 211 in 1943. The cause for the most part is reported as known.

ROBERT O. BLOOD, Chairman
BENJAMIN P. BURR
MARION FAIRFIELD

Dr. Robinson expressed the sincere recognition of the Committee on Officers' Reports of the invaluable service rendered to the welfare of the State by the Committee on Maternity and Infancy. He said it believed that this committee renders likewise an invaluable service to every conscientious physician practicing obstetrics, both in New Hampshire and throughout the civilized world. Such statistical reports, carefully analyzed, he continued, should serve as the most solid available foundation on which physicians can build for the betterment of methods of obstetric care. He therefore urged every member of the Society to give this committee his fullest co-operation as the occasion may arise, scientifically and without prejudice. He moved the acceptance of this report, and the motion was duly seconded and carried.

Dr. Sycamore then presented the following report:

Report of the Committee on Medical Economics

New Hampshire Physician Service. The past year has seen the fruition of the project toward which your committee had directed the major portion of its labors in the preceding three years, ably assisted by the officers of the Society and the House of Delegates. On August 1, 1944, the New Hampshire Physician Service issued its first contracts, and since then has proved to be a lusty offspring, on which this committee has kept a paternal eye, although, of course, with the completion of incorporation, control and authority passed to the hands of the Board of Trustees of the New Hampshire Physician Service. An account of the operations of the plan to date is given in the report of its president.

Your committee has noted with interest the endorsement of medical-service plans given by the American Medical Association and the National Physicians' Con-

mittee. At the annual meeting of the American Medical Association last June, the report of the Committee on Medical Service and Public Relations, later accepted by the House of Delegates, stated "All constituent state associations have been urged to develop voluntary plans [for medical expense insurance] within their territory. The American Medical Association will assist in the development, correlation and integration of such plans." It is evident, therefore, that the New Hampshire Medical Society, in constituting the New Hampshire Physician Service, has acted in accordance with the considered judgment of our national association.

National Physicians' Committee The National Physicians' Committee has directed its efforts in the past year first to conducting a public opinion poll that indicated a preference for voluntary sickness insurance over national compulsory insurance, and second, to promoting a campaign for the extension of such voluntary insurance of any type. Because some members of our society have expressed a certain degree of doubt as to the validity of the publicity and methods of the National Physicians' Committee, your committee recommends, as it did last year, that the question of financial support for this organization be left to each physician.

Association of American Physicians and Surgeons A new organization has entered the field of medical economics and public relations, originally organized under the above name by the Lake County (Indiana) Medical Society and now claiming membership in all states, with endorsement by several county societies. The main purpose of the association appears to be an unalterable antagonism to any form of a governmental national health program, using as a weapon a professional boycott against any such program and against any fellow physicians who might co-operate with the program. Your committee recognizes the right of physicians to so organize, however, it is our belief that it is not expedient to approve so completely a closed-minded attitude as this organization insists on, for reasons that we think will become evident in the discussion of national compulsory sickness insurance. We also find it difficult to justify on the basis of this organization's acknowledged activities, the annual dues of \$10.00 necessary to continuing membership therein.

National compulsory sickness insurance It is expected that a modified version of the Wagner-Murray-Dingell Bill will be introduced into the present Congress, undoubtedly incorporating some of the proposals advanced by the present Pepper Committee on Wartime Health and Education. Your committee believes that we should make no blanket condemnation before the fact, but should be prepared to make a careful evaluation of any such bill on its merits. We believe, furthermore, that governmental participation in the economic aspects of medical service may conceivably become expedient and desirable. There is merit, for example, in the regional organization of hospitals and health centers, with government assistance in providing the necessary facilities. Under such a plan the smaller diagnostic health centers and hospitals are integrated with progressively larger units so that necessary consulting and special services are readily available to all. A logical extension of such regional organization is the development of group practice around the hospitals. The medical profession, we believe, will contribute more to its own and the public welfare by indicating its readiness to confer with governmental agencies in an attempt to work out a mutually satisfactory solution than by assuming an uncompromising antagonism to any such attempt. We would point out that the existence in New Hampshire of a strong and widely inclusive voluntary prepaid-medical-care program under the auspices of the New Hampshire Medical Society would be a cogent argument, in any discussion, for the capability of the medical profession in our state to handle the professional aspects of medical care, and we therefore bespeak the vigorous support of all members of the Society for the New Hampshire Physicians Service.

L. K. STAMORE *Chairman*
FRANCIS J. C. DUBE
R. W. ROBINSON

Dr Robinson said that the Committee on Officers' Reports had no special comment to make on the above report. For himself and the members of his committee, he approved each part of it, except that he detected a feeling, not quite unanimous, that it indicated a little too much willingness to participate in plans of the federal government for socialized medicine. He was willing to defend the report, but had no other to make.

Dr Dube moved the acceptance of the report, and his motion was duly seconded and carried.

Dr Bowler then presented the following report

Report of the Committee on Medical Education and Hospitals

The activities of this committee during the past year have been extremely limited, owing to conditions at this time that have permitted no program of post-graduate study. The Commonwealth Fund fellowships have been discontinued for the duration of the war.

The Speakers' Bureau has been used by a few county societies, but this program has necessarily been restricted as well.

The New England Regional Committee of the Wartime Graduate Medical Program has continued in operation, and on it this committee has been represented. The services of several men in the Society have been utilized in connection with this program in lectures and demonstrations at various station hospitals in this region.

Quite recently a commission has been named by Governor Charles M. Dale for the survey of hospital facilities in New Hampshire. The appointment of this committee follows the outline of Senate Resolution No. 191, a bill providing for a national survey of hospitalization facilities, to be on a state basis. This commission is representative of various groups interested and concerned in the general problem of health and hospitalization and to it have been appointed Dr George C. Wilkins, of Manchester, and the chairman of this committee. It is entirely possible that out of this survey may develop more activities on the part of this committee.

JOHN P. BOWLER, *Chairman*
JAMES W. JAMESON
HERBERT L. TAYLOR

Dr Robinson moved the adoption of this report. The motion was duly seconded and carried.

Dr Powers then presented the following report

Report of the Committee on Public Health

This is the third anniversary of the Committee on Public Health. For the past year the Committee has consisted of Dr Anthony E. Peters, of Portsmouth, Dr Clinton R. Mullins, of Concord, and Dr Harris E. Powers, of Manchester, the latter serving as chairman. It has been the function of this committee to keep in touch with the public-health activities in our state, and to keep abreast of the functions of other public-health units in the scattered sections of the country. This has been accomplished by communications from the Committee on Public Health of the American Medical Association and by direct contact with the workers in our own community.

Again this past year our industries have been pressed hard in securing employees, owing to the urgency of the war demands. In many instances we have had to resort to older men, and men who are less well physically qualified for the arduous duties they have had to carry on. Both employer and employee have labored under extenuating circumstances, tension has been high, and with these facts

Maternal Mortality

There were 26 maternal deaths and 8695 live births, a maternal mortality rate of 2.99 per 1000 live births. This may be compared with the figures for 1943 of 24 maternal deaths and 9825 live births, a maternal mortality rate of 2.44 per 1000 live births. Over a period of ten years, the highest mortality was that of 1935, 6.1 per 1000 live births, with 45 deaths, the lowest was that of 1942, 1.6, with 15 deaths.

The 26 maternal deaths have been classified according to the *International List of Causes of Death*, as follows:

CLASSIFICATION	NO OF DEATHS
Puerperal toxemia (death after delivery)	9
Infection during childbirth and puerperium	7
Accidents of pregnancy (death before delivery)	5
Inversion of uterus	2
Hemorrhage (1 before delivery and 1 after)	2
Ectopic gestation	1
Total	26

The committee has reclassified these for the purpose of this report in the following way:

CAUSE OF DEATH

Accidents of pregnancy	11
Puerperal emboli	4
Anesthesia	2
Inversion of uterus (with hemorrhage)	2
Attempted abortion with poison	1
Cerebral embolus (before delivery, cause unknown)	1
Multiple pulmonary emboli due to meconium and amniotic fluid (before delivery)	1
Hemorrhage	2
Internal hemorrhage	1
Probable placenta previa (case seen only by coroner)	1
Toxemia (all types)	9
Puerperal sepsis	3
Ruptured ectopic pregnancy	1
Total	26

The committee has further classified these cases on the basis of data submitted in one of three groups: unavoidable, patient's fault and probably avoidable. There were reports on 5 deaths that gave insufficient data for classification. In 2 of these, one eclampsia and the other puerperal infection, no information was submitted. The other 3 deaths were recorded on the certificate as due to postpartum eclampsia, eclampsia and internal hemorrhage, respectively. The remaining 21 cases were classified as follows: unavoidable, 11; patient's fault, 6; avoidable, 4. Of the 11 deaths classified as unavoidable, 6 were due to embolism, 2 to inversion of the uterus, 2 to toxemia and 1 to ectopic gestation. Of the 6 deaths classified as the patient's fault, — that is, she failed to seek medical attention or failed to carry out medical advice, — 3 were due to toxemia and 1 to hemorrhage, probably placenta previa, in 1 case the actual cause of death was pneumonia following a normal delivery when the patient left the hospital against advice, and in 1 case death was due to poison from drinking oil of cedar in an attempt to abort. Of the 4 deaths classified as probably avoidable, 2 were due to anesthesia. The committee is of the opinion that, with the difficulty at the present in securing physicians to give anesthesia, the attending physician must assume the responsibility for it and be more careful and attentive to the procedure. There was 1 death due to toxemia that the committee thought might have been avoided had adequate treatment been given. One patient died of postoperative complications following a cesarean section. In this case some of the committee believed that the procedure of choice would have been to allow the patient to deliver normally.

All the deliveries took place in a hospital.

The deaths by county were as follows: Belknap, 2; Carroll, 1; Cheshire, 1; Grafton, 2; Hillsborough, 8; Merrimack, 2; Rockingham, 3; Strafford, 6; and Sullivan, 1. Coos County is the only one having no maternal deaths.

The committee has certain recommendations to make, and these will appear later in detail in a printed report, copies of which will be sent to each member. Briefly the points are as follows:

The value of Rh-factor typing in obstetric patients and having facilities available for typing in hospital laboratories.

The value of autopsies, with an increasing effort on the part of physicians to obtain an autopsy.

The increased responsibility of the attending physician in giving patients in labor an anesthetic.

The treatment in toxemias. (There is evidence that physicians still fail to give adequate and proper treatment in toxemias. Toxemia is still highest on the list as a cause of maternal deaths. The treatment in toxemias cannot be overstressed.)

Infant Mortality

Included in this group are those infants who died under one year of age. There were 322 infant deaths in 1944, giving an infant death rate of 37.0 per 1000 live births, as compared with 420 deaths in 1943, a rate of 42.9. Prematurity as a single cause still accounts for the largest number of deaths.

Stillbirths

There were 232 stillbirths in 1944, as compared with 211 in 1943. The cause for the most part is reported unknown.

ROBERT O. BLOOD, Chairman
BENJAMIN P. BURPEE
MARION FAIRFIELD

Dr. Robinson expressed the sincere recognition of the Committee on Officers' Reports of the invaluable service rendered to the welfare of the State by the Committee on Maternity and Infancy. He said it believed that this committee renders likewise an invaluable service to every conscientious physician practicing obstetrics, both in New Hampshire and throughout the civilized world. He therefore urged every member of the Society to give this committee his fullest co-operation as the occasion may arise, scientifically and without prejudice. He moved the acceptance of this report, and the motion was duly seconded and carried.

Dr. Sycamore then presented the following report:

Report of the Committee on Medical Economics

New Hampshire Physician Service. The past year has seen the fruition of the project toward which your committee had directed the major portion of its labors in the preceding three years, ably assisted by the officers of the Society and the House of Delegates. On August 1, 1944, the New Hampshire Physician Service issued its first contracts, and since then has proved to be a lusty offspring, on which this committee has kept a paternal eye, although, of course, with the completion of incorporation, control and authority passed to the hands of the Board of Trustees of the New Hampshire Physician Service. An account of the operations of the plan to date is given in the report of its president.

Your committee has noted with interest the endorsement of medical-service plans given by the American Medical Association and the National Physicians' Com-

mittee. At the annual meeting of the American Medical Association last June, the report of the Committee on Medical Service and Public Relations, later accepted by the House of Delegates, stated "All constituent state associations have been urged to develop voluntary plans [for medical expense insurance] within their territory. The American Medical Association will assist in the development, correlation and integration of such plans." It is evident, therefore, that the New Hampshire Medical Society, in constituting the New Hampshire Physician Service, has acted in accordance with the considered judgment of our national association.

National Physicians' Committee The National Physicians' Committee has directed its efforts in the past year first to conducting a public opinion poll that indicated a preference for voluntary sickness insurance over national compulsory insurance, and second, to promoting a campaign for the extension of such voluntary insurance of any type. Because some members of our society have expressed a certain degree of doubt as to the validity of the publicity and methods of the National Physicians' Committee, your committee recommends, as it did last year, that the question of financial support for this organization be left to each physician.

Association of American Physicians and Surgeons A new organization has entered the field of medical economics and public relations, originally organized under the above name by the Lake County (Indiana) Medical Society and now claiming membership in all states, with endorsement by several county societies. The main purpose of the association appears to be an unalterable antagonism to any form of a governmental national health program, using as a weapon a professional boycott against any such program and against any fellow physicians who might co-operate with the program. Your committee recognizes the right of physicians to so organize, however, it is our belief that it is not expedient to approve so completely a closed-minded attitude as this organization insists on, for reasons that we think will become evident in the discussion of national compulsory sickness insurance. We also find it difficult to justify, on the basis of this organization's acknowledged activities, the annual dues of \$10.00 necessary to continuing membership therein.

National compulsory sickness insurance It is expected that a modified version of the Wagner-Murray-Dingell Bill will be introduced into the present Congress, undoubtedly incorporating some of the proposals advanced by the present Pepper Committee on Wartime Health and Education. Your committee believes that we should make no blanket condemnation before the fact, but should be prepared to make a careful evaluation of any such bill on its merits. We believe, furthermore, that governmental participation in the economic aspects of medical service may conceivably become expedient and desirable. There is merit, for example, in the regional organization of hospitals and health centers, with government assistance in providing the necessary facilities. Under such a plan the smaller diagnostic health centers and hospitals are integrated with progressively larger units, so that necessary consulting and special services are readily available to all. A logical extension of such regional organization is the development of group practice around the hospitals. The medical profession, we believe, will contribute more to its own and the public welfare by indicating its readiness to confer with governmental agencies in an attempt to work out a mutually satisfactory solution than by assuming an uncompromising antagonism to any such attempt. We would point out that the existence in New Hampshire of a strong and widely inclusive voluntary prepaid-medical-care program under the auspices of the New Hampshire Medical Society would be a cogent argument, in any discussion, for the capability of the medical profession in our state to handle the professional aspects of medical care, and we therefore bespeak the vigorous support of all members of the Society for the New Hampshire Physicians Service.

L. K. SYCAMORE, *Chairman*
FRANCIS J. C. DUBE
R. W. ROBINSON

Dr. Robinson said that the Committee on Officers' Reports had no special comment to make on the above report. For himself and the members of his committee, he approved each part of it, except that he detected a feeling, not quite unanimous, that it indicated a little too much willingness to participate in plans of the federal government for socialized medicine. He was willing to defend the report, but had no other to make.

Dr. Dube moved the acceptance of the report, and his motion was duly seconded and carried.

Dr. Bowler then presented the following report:

Report of the Committee on Medical Education and Hospitals

The activities of this committee during the past year have been extremely limited, owing to conditions at this time that have permitted no program of post-graduate study. The Commonwealth Fund fellowships have been discontinued for the duration of the war.

The Speakers' Bureau has been used by a few county societies, but this program has necessarily been restricted as well.

The New England Regional Committee of the Wartime Graduate Medical Program has continued in operation, and on it this committee has been represented. The services of several men in the Society have been utilized in connection with this program in lectures and demonstrations at various station hospitals in this region.

Quite recently a commission has been named by Governor Charles M. Dale for the survey of hospital facilities in New Hampshire. The appointment of this committee follows the outline of Senate Resolution No. 191, a bill providing for a national survey of hospitalization facilities, to be on a state basis. This commission is representative of various groups interested and concerned in the general problem of health and hospitalization and to it have been appointed Dr. George C. Wilkins, of Manchester, and the chairman of this committee. It is entirely possible that out of this survey may develop more activities on the part of this committee.

JOHN P. BOWLER, *Chairman*
JAMES W. JAMESON
HERBERT L. TAYLOR

Dr. Robinson moved the adoption of this report. The motion was duly seconded and carried.

Dr. Powers then presented the following report:

Report of the Committee on Public Health

This is the third anniversary of the Committee on Public Health. For the past year the Committee has consisted of Dr. Anthony E. Peters, of Portsmouth, Dr. Clinton R. Mullins, of Concord, and Dr. Harris E. Powers, of Manchester, the latter serving as chairman. It has been the function of this committee to keep in touch with the public-health activities in our state, and to keep abreast of the functions of other public-health units in the scattered sections of the country. This has been accomplished by communications from the Committee on Public Health of the American Medical Association and by direct contact with the workers in our own community.

Again this past year our industries have been pressed hard in securing employees, owing to the urgency of the war demands. In many instances we have had to resort to older men, and men who are less well physically qualified for the arduous duties they have had to carry on. Both employer and employee have labored under extenuating circumstances, tension has been high, and with these facts

in mind it is not unreasonable to presume that differences of opinion between labor and management might occur frequently. In our state, however, co-operation appears to have been excellent, and only minor instances have occurred to delay the war effort. Part of the credit for this is due to the progress of industrial health within the state boundaries. The State Board of Health, with a limited group of employees, has made repeated inspections of industrial sites and offered its assistance in maintaining the highest possible working standards. Its co-operation has been accepted, and in most instances the progress of industrial health in New Hampshire has been moving steadily forward. Our problems have not all been solved, but we are making progress.

As an illustration, the chairman of this committee had the privilege in August, 1944, of making a tour of inspection of the northern section of the State, together with Dr. Alfred Frechette, State Health Officer, and Captain Forrest Bumford, acting director of the Division of Industrial Hygiene. This trip was made primarily for the purpose of gaining firsthand knowledge of how the State Board of Health functions, especially in the field of industrial hygiene. The trip took us through the north country, where we inspected the Brown Manufacturing Company at Berlin. It was indeed a surprise to go over the holdings of this company and learn something of how the lumber industry functions. We followed the process from breakfast to supper, starting out with the men and watching their activities throughout the day. We had the opportunity of going through the quarters of the lumberjacks, inspecting the mess shacks and examining the refrigeration plants. Dr. Samuelson, who serves as the medical director of the company, acted as our guide and escorted us through several of the camp sites. He took us through the infirmary and advised us of the care the employees were given in both sickness and injury. In the pulp mills, where a large number of chemicals are used in the processing of lumber, I learned that injurious gases are constantly given off and that unless precautions are taken the health of the employees may be seriously impaired. I watched the study of such problems through chemical tests taken over a period of twenty-four hours under actual working conditions and was interested in the methods suggested by the State Board of Health for overcoming these hazards.

Complicated surveys of similar character are constantly being made by the State Board of Health to increase the efficiency of employees by improving sanitary conditions under which they work. One does not have to go back many years to find a time when such activities would have been considered extravagant and unnecessary, but the profession is fast becoming conscious of the necessity of preserving the health of labor and the safety of the citizens.

This brings up another extremely important problem that must sooner or later be faced, very little has been done in the resort sections of the State to ensure proper health standards among vacationists, and as the tourist trade grows and overnight camp and trailer sites increase in number, sanitary conditions about these areas are certainly going to demand more direct supervision.

The Society owes a debt of gratitude to the State Board of Health, which at the present time is functioning with a limited personnel and under somewhat trying circumstances owing to the lack of suitable housing facilities. The various departments are scattered among several buildings, and co-ordination under such an arrangement is difficult. Our moral support for suitable housing facilities for the State Board of Health as a unit will aid materially in obtaining such quarters and will improve the efficiency of the department. Public health is primarily a medical problem, and it is our duty as physicians to keep it that way.

It has been a pleasure and privilege to serve as your representatives on this committee for the past year.

HARRIS E. POWERS, *Chairman*
ANTHONY E. PETERS
CLINTON R. MULLINS

Dr. Robinson said that the Committee on Officers' Reports found much of interest in the report of the Committee on Public Health. It recommended

commendation of the State Board of Health of its efficient performances, especially in the cause of industrial hygiene, by the House of Delegates. The committee suggested that the House go on record as approving, when betterment of personnel makes it practicable, more rigid sanitary protection for the users of recreational facilities. He moved the acceptance of this portion of the report. This motion was duly seconded and carried.

Dr. Robinson likewise moved that the House of Delegates go on record as being in favor of more efficient housing of the State Board of Health than is now employed. He moved the acceptance of this portion of the report, and the motion was duly seconded and carried.

Dr. Smith then presented the following report:

Report of the Delegates to the House of Delegates, American Medical Association

The annual session of the House of Delegates of the American Medical Association was held at Chicago in June, 1944. It was well attended, especially by the doctors in the services. Your delegate served as chairman of the Reference Committee on Credentials. Emphasis throughout the meetings was on the war and subjects allied to it.

The Committee on Postwar Medical Service, appointed to assist veterans in location and post-graduate work, reported that questionnaires had been sent to all medical officers asking them what they wanted after the war as refresher courses, internships, residencies and so forth. Plans should be made to assist the veterans in obtaining this post-graduate work and in their relocation. Accordingly, it is recommended that this society establish a Committee on Postwar Medical Service, to work with the similar committee of the American Medical Association. The establishment of a loan fund by the Society, to be administered by this committee or by the trustees, or both, should be considered. Loans to returning medical officers may prove of material assistance in re-establishing themselves in their practice.

The general program of Emergency Maternal and Infant Care was approved, but the methods of payment were disapproved. It was recommended that the program be transferred from the Department of Labor to the Department of Public Health, and that full control and regulation of it be placed completely in the public-health department of each state.

The Council on Medical Service and Public Relations has established a Washington office. It has studied proposed legislation, voluntary insurance diagnostic clinics and medical-service bureaus, and has collected information and data concerning all aspects of medical care. Bulletins of the activities of the council have been sent to the county and state societies, and the information collected is available to all.

Dr. Kretschmer suggested that the family physician should take a more active part in the education of the public in social medical questions. "It would be well," he said, "if every member of the profession would make a personal effort to explain to patients, whenever the opportunity offers or can be made, the problems with which medicine is faced, and particularly the results of governmental dictation and supervision of medical practice."

New England was honored by the election of Roger I. Lee, of Boston, as president-elect of the Association. The 1945 session has been canceled, although it is expected that the House of Delegates will meet in Chicago in the fall. Extensive plans are in preparation for the one hundredth anniversary of the American Medical Association in 1947. It is hoped that either the war will be over or conditions will have so changed that a proper celebration may be held at Atlantic City.

An effort has been made in this report to bring to your attention some of the high lights of the meeting. The complete proceedings have been published as usual in the *Journal of the American Medical Association*.

DEERING G. SMITH

Dr Robinson for the Committee on Officers' Reports paid tribute to the ability and excellent service rendered to the state and national societies by Dr Smith. He moved the acceptance of this portion of the report, and the motion was duly seconded and carried.

Dr Robinson then spoke as follows:

Regarding the creation, on the part of the New Hampshire Medical Society, of a loan fund as an aid to the re-establishment within the State of physicians returning from service in the armed forces, we, of course, are in complete approval of the sentiment that fathers this idea, but believe that the size of such a fund as might be raised within our abilities would bear little practical significance when compared with the size of the service that it was fostered to perform, though its actual benefit would be small and that the potentialities toward the production of ill-feeling might be large.

We believe that it is intended that such funds be made available as a part of postwar nation-wide planning and, if not, that local banking facilities will be readily available to physicians for such purposes, as they have in the past.

We think that the Society should approve the appointment of a Committee on Postwar Medical Service to co-operate with the similar committee of the American Medical Association. We suggest that this committee be appointed by the chair, and not be elective. We recommend that it have a member from each county in the State, and that one of these be a member of the Committee on Medical Preparedness and another a member of the Committee on Medical Education and Hospitals. We believe, likewise, that each appointee should have the ratification of his own county society. We move the acceptance of this portion of our report.

This motion was duly seconded and carried.

Dr Robinson then said:

We approve the transference of the program of Emergency Maternal and Infant Care from the Department of Labor to the Department of Public Health, and the proposal that the full control and regulation of this plan in the State of New Hampshire shall remain completely in our own State Board of Health. We believe that the value of public education on social medical questions by individual physicians to their individual patients cannot be overemphasized, and recommend that the words of Dr Kretschmer, as quoted in our delegate's report, be read at the General Assembly. We move the acceptance of this portion of our report.

This motion was duly seconded and carried.

(To be concluded)

CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

BENJAMIN CASTLEMAN, M.D., *Acting Editor*

EDITH E. PARRIS, *Assistant Editor*

CASE 31341

PRESENTATION OF CASE

A forty-three-year-old woman entered the hospital complaining of dysphagia.

Six weeks before admission, while eating, she was seized with a sudden, severe lower substernal pain radiating to the right scapular region. For several days she felt generally miserable. The pain slowly subsided, but thereafter she found that ingestion of food brought on a similar attack, and she therefore did not partake of any solid food. She had no difficulty with fluids. There was no nausea or vomiting. The pain usually lasted one or two hours. On one occasion it persisted all night and the patient could not lie down.

She had had an attack of "pleurisy" four years

*On leave of absence

before entry and again three years later. One sister had died of pulmonary tuberculosis.

Physical examination revealed a well developed, well nourished woman in no acute distress. There was deafness in the left ear, and a diaphragm that seemed to be high on the right. The feet were cold and clammy, and the dorsalis pedis arteries were not palpable. Otherwise, the examination was negative.

The temperature was 99°F, the pulse 70, and the respirations 20. The blood pressure was 125 systolic, 85 diastolic.

Examination of the blood showed a white-cell count of 8200, with 69 per cent neutrophils, 23 per cent lymphocytes, 7 per cent monocytes and 1 per cent eosinophils, the hemoglobin was 13.6 gm. The nonprotein nitrogen was 30 mg. per 100 cc., the chloride 106 milliequiv. per liter, and the total protein 6.5 gm. per 100 cc. The urine gave a + test for albumin, and the sediment contained 5 white cells and a rare coarsely granular cast per high-power field.

An x-ray film taken outside the hospital showed a pressure defect 3.5 cm. in length in the barium-filled esophagus, this defect was anteriorly placed at the level of the carina. The normal mucosal pattern could be traced through it, and no ulcer was apparent. The mass caused no great obstruction to the passage of barium. The stomach and duodenum appeared normal in form and function.

On the seventh hospital day an operation was performed.

in mind it is not unreasonable to presume that differences of opinion between labor and management might occur frequently. In our state, however, co-operation appears to have been excellent, and only minor instances have occurred to delay the war effort. Part of the credit for this is due to the progress of industrial health within the state boundaries. Dr. Smith then presented the following report

Report of the Delegates to the House of Delegates, American Medical Association

The annual session of the House of Delegates of the American Medical Association was held at Chicago in June, 1944. It was well attended, especially by the doctors in the services. Your delegate served as chairman of the Reference Committee on Credentials. Emphasis throughout the meetings was on the war and subjects allied to it.

The Committee on Postwar Medical Service, appointed to assist veterans in location and post-graduate work, reported that questionnaires had been sent to all medical officers asking them what they wanted after the war: refresher courses, internships, residencies and so forth. Plans should be made to assist the veterans in obtaining this post-graduate work and in their relocation. Accordingly, it is recommended that this society establish a Committee on Postwar Medical Service, to work with the similar committee of the American Medical Association. The establishment of a loan fund by the Society, to be administered by this committee or by the trustees, or both should be considered. Loans to returning medical officers may prove of material assistance in re-establishing themselves in their practice.

The general program of Emergency Maternal and Infant Care was approved, but the methods of payment were disapproved. It was recommended that the program be transferred from the Department of Labor to the Department of Public Health, and that full control and regulation of it be placed completely in the public-health department of each state.

The Council on Medical Service and Public Relations has established a Washington office. It has studied proposed legislation, voluntary insurance diagnostic clinics and medical-service bureaus, and has collected information and data concerning all aspects of medical care. Bulletins of the activities of the council have been sent to the county and state societies, and the information collected is available to all.

Dr. Kretschmer suggested that the family physician should take a more active part in the education of the public in social medical questions. "It would be well," he said, "if every member of the profession would make a personal effort to explain to patients, whenever the opportunity offers or can be made, the problems with which medicine is faced, and particularly the results of governmental dictation and supervision of medical practice."

New England was honored by the election of Roger I. Lee, of Boston, as president-elect of the Association. The 1945 session has been canceled, although it is expected that the House of Delegates will meet in Chicago in the fall. Extensive plans are in preparation for the one hundredth anniversary of the American Medical Association in 1947. It is hoped that either the war will be over or conditions will have so changed that a proper celebration may be held at Atlantic City.

(Fig 1) The only further comment that might be made is that there does not seem to be much swelling of the mucosa as it passes from the defect, nor does there seem to be rigidity of the wall—it is quite flexible. This large film quite well rules out a hiatus hernia.

DR SCHALL The x-ray films demonstrate that there is a normal esophageal wall. There is no infiltration of the wall, but there is an extrinsic mass. In this view here, the right and left main-stem bronchi are patent and there is no broadening of the carina. Therefore, from the x-ray films one can say that this patient had a mass involving the esophageal wall, and that brings up the possibility of a benign new growth of the esophagus. There is no mention in the history of the Hinton test.

DR. CASTLEMAN It was negative.

DR. SCHALL Gummas of the esophagus are rare. A sister had died of tuberculosis. I assume that there was no evidence of pulmonary tuberculosis in this patient. I do not believe that this was a tuberculoma. I am inclined to think that this was a benign tumor of the esophageal wall, perhaps a tumor arising from the muscle—a leiomyoma.

DR. S. A. THEODORE Could this have been a fibroma originating in the mediastinum?

DR. CASTLEMAN That is a possibility. We have also seen intramural neurofibromas of the esophagus.

DR. HELEN PITTMAN Perhaps it is one of the intramural extramucosal tumors of the esophagus that Dr. Schatzki used to talk about*.

CLINICAL DIAGNOSIS

Carcinoma of esophagus?

DR. SCHALL'S DIAGNOSIS

Benign tumor of esophageal wall (leiomyoma?)

ANATOMICAL DIAGNOSIS

Tuberculosis of mediastinal lymph nodes

PATHOLOGICAL DISCUSSION

DR. CASTLEMAN Dr. Richard Sweet operated on this patient. He had a great deal of difficulty exposing the lesion because of dense fibrous adhesions over the lung. When he separated these, he found a calcified focus on the pleura, which he thought was due to old tuberculosis. When he pushed the lung aside and got to the region of the esophagus, it was obvious that the mass was composed of an aggregation of enlarged lymph nodes that was pressing on the esophagus. He was able to remove them without entering the esophagus. At the operation a frozen section of one of the lymph nodes showed active tuberculosis. The nodes were removed to free up the obstruction, but nothing further was attempted. The patient is doing well.

The sections showed microscopically the character-

istic caseation and Langhans giant cells of active tuberculosis. There apparently was no active tuberculosis in the lungs.

CASE 31342

PRESENTATION OF CASE

A five-day-old girl was admitted to the hospital because of vomiting since birth.

The infant was delivered with low forceps at term after a prolonged first stage of labor that lasted three days. The birth weight was 6 pounds, 2 ounces. She appeared normal at birth but began to vomit green material during the first night and continued to vomit at frequent intervals until admission. She passed normal meconium twice, then the stools became blue gray, and shortly before admission they became yellow. During the three days before admission the abdomen was markedly distended. She voided at least twice a day. The formula, which could not be retained, was supplemented by small subcutaneous clyses. Barium was given by mouth in the maternity hospital, but no abnormality was observed.

Physical examination revealed a slightly jaundiced, moderately dehydrated infant with a lusty cry, weighing 5 pounds, 12 ounces. The cranial sutures were over-riding, and the fontanelles were sunken. The abdomen was markedly distended, and peristalsis was practically absent. The cord was normal. The heart and lungs were normal. She vomited fecal material and passed by rectum small amounts of fluid with tiny particles of solid yellow stool.

The temperature was normal, the pulse 140, and the respirations 19.

Examination of the blood showed a red-cell count of 4,200,000, with 13.2 gm of hemoglobin. The cells and platelets appeared normal. The white-cell count was 6600, with 20 per cent neutrophils, 68 per cent lymphocytes and 12 per cent monocytes. The urine was normal. The blood was Rh negative.

An x-ray examination showed the abdomen to be distended. There appeared to be free air scattered throughout the peritoneal cavity. There were numerous small areas of calcification. There was opaque material in the stomach and in one loop of bowel.

The infant was promptly started on measures of hydration preparatory to operation, but she died before operation could be performed.

DIFFERENTIAL DIAGNOSIS

DR. ALLAN M. BUTLER We have an infant who began to vomit green material during the first day of life and continued to vomit at frequent intervals until admission, which, unfortunately, was not until five days later.

*Schatzki R., and Hawes L. E. Roentgenological appearance of extramucosal tumors of the esophagus. *Am J Roentgenol* 48:1-15, 1942.

DIFFERENTIAL DIAGNOSIS

DR LEROY A SCHALL The history of this case, although short, brings out several positive facts. First, there was severe substernal pain, which radiated to the right scapula, and then following the pain the patient had difficulty in swallowing. Whether this pain was due to obstruction or caused by eating is not brought out in the history. She had no difficulty with liquids. There was no apparent loss of weight on admission, nor had there been nausea or vomiting. There is no mention of regurgitation nor of belching, or of whether, if there was belching, this relieved the pain.

DR BENJAMIN CASTLEMAN She had occasional regurgitation but no nausea or vomiting.

DR SCHALL The pain was of long duration, at least several hours, and on one occasion it lasted all night. The patient noticed that lying down aggravated the pain. That is an important observation, but I should like to know whether swallowing while lying down caused pain.

From the history we have a story of pain followed by difficulty in swallowing. It would be well to consider what causes substernal pain and difficulty in swallowing. It has been estimated that at least 3 or 4 per cent of patients seeing a cardiologist because of substernal pain have pain due to disease of the gastrointestinal tract. In one series, a fifth of these gastrointestinal cases were due to disease of the esophagus. Could this be esophagospasm or cardiospasm? In these conditions, in contradistinction to angina, the pain is not related to effort. Atropine is beneficial. The pain in esophagospasm is of long duration, and x-ray examination demonstrates a dilated esophagus. When this dilated esophagus fills the patient may complain of a heavy substernal sensation and there may be regurgitation of food, which may be interpreted as vomiting, there may also be cough due to spilling over into the larynx. Pain and difficulty in swallowing may be due to congestion of the esophagus. In this condition the pain occurs in the recumbent position, and along with it there is difficulty in swallowing. Pain and difficulty in swallowing can be due to carcinoma of the esophagus, but in this condition the difficulty in swallowing usually comes first, there is a gradual closing of the esophagus due to the new growth, and the pain develops late. In this patient's history pain came first and then difficulty in swallowing. There was no cachexia, so that she probably had not had difficulty in swallowing over a long period of time. Esophageal hiatus hernia, that is, a hernia through the esophageal opening of the diaphragm, is usually painless, but it may start with pain, particularly if it is associated with an ulcer of the lower end of the esophagus or of the stomach. Difficulty in swallowing in esophageal hiatus hernia is not frequent but it may be present. In peptic ulcer of the esophagus the pain develops early and the difficulty in swallowing

comes later. The pain is substernal, and it may be referred to the epigastrium. It may also be referred to the dorsal spine, and occasionally it is widespread. Rarely the pain is referred to the ear, the face and the neck. Cases have also been described of esophageal ulcer with pain referred to the shoulder, arm and hand, but in contradistinction to anginal pain, the pain is present over the radial surface of the hand. The pain in esophageal ulcer is precipitated by swallowing and is worse in the recumbent position, because these ulcers are usually low in the esophagus and regurgitation of gastric secretion pre-

FIGURE 1

cipitates the pain. Diverticulum of the esophagus is usually without pain, but there is a sensation of pressure. It fills up, and then it may cause difficulty in swallowing merely by the filled pouch pressing on the esophagus. A traction diverticulum is usually discovered on routine x-ray examination. The patient rarely has symptoms, and there is often a history of mediastinal tuberculosis or tuberculosis of the spine.

Then we come to the x-ray interpretation. From the history as it is given, although it is stated that x-ray examination showed no apparent ulcer, I am inclined to think that this was an esophageal ulcer.

DR MILFORD D SCHULZ Ulcers of the esophagus are not always found.

DR SCHALL I know it. I am basing my diagnosis on the symptoms.

DR SCHULZ Here is the critical area, and the films taken in this hospital show the lesion described

ANATOMICAL DIAGNOSES

Small intestinal obstruction (jejunal), due to congenital diaphragm
Meconium peritonitis

PATHOLOGICAL DISCUSSION

DR CASTLEMAN It is unfortunate that this child was not brought into the hospital sooner and operated on, because at autopsy we found a lesion that surgically could have been removed, with probable cure of the patient. About 30 cm below the ligament of Treitz was a marked narrowing. The jejunum and duodenum above the obstruction were 5 cm in diameter, then the jejunum narrowed down to about 1 cm in diameter. At that point there was a diaphragm, in the center of which was an opening about 1 mm in diameter, the bowel beyond it was collapsed. This obviously was a congenital abnormality, which, during fetal life, had produced obstruction and a rupture somewhere above it. We were unable to find the point of perforation at autopsy, and this is almost the rule in these cases. We found numerous areas of calcification, practically all limited to the surface of the right lobe of the liver. We could not find any on the surface of the intestines, either grossly or microscopically, so that the perforation probably occurred in the duodenum close to the right lobe of the liver.

Microscopically the diaphragm was made up of connective tissue, with mucosa on each side and no muscle layer. The capsule of the liver was markedly thickened, and in it were the areas of calcification that were seen on the x-ray films. Surrounding some of them were cornified epithelial cells, and in one section there was a suggestion of true bone formation.

DR SIDNEY FARBER I should like to express my agreement with Dr Butler's conclusions and also with Dr Castleman's opinion that this process may go on to bone formation. When the site of perforation can be demonstrated, it is usually found about 10 cm proximal to the point of obstruction.

Dr Butler mentioned meconium ileus. There are two kinds. One type is caused by inspissated meconium produced by partial obstruction such

as that caused by stenosis at the ileocecal valve. Dehydration accounts for the inspissation. The pancreatic enzymes are normal. The second type or true meconium ileus is caused by failure of the pancreatic enzymes to enter the duodenum. The most frequent cause is atresia or stenosis of the pancreatic ducts. The abnormal meconium in such patients is so thick and mucilaginous that normal passage through the intestinal tract is impossible. Fatal intestinal obstruction within two or three days after birth is an invariable result of such obstruction. The abnormal meconium in patients with pancreatic achylia and true meconium ileus may be put into a watery condition in a test tube quite readily when mixed with a 1 per cent solution of pancreatin. In several cases Dr Robert Gross has been able to relieve the intestinal obstruction in babies with true meconium ileus by instilling into the small intestine such a solution of pancreatin. Complete relief of the intestinal obstruction took place, although intercurrent infection caused death days to weeks after the obstruction had been relieved. This method of therapy should be productive of successful results.

DR BUTLER Ladd and Gross⁴ give an excellent summary of the embryonic origin of diaphragms, persistence of which leads to partial rather than complete obstruction. In their book is a picture of a diaphragm that is identical with the one noted here.

DR CASTLEMAN Dr Schulz, is not this x-ray appearance pathognomonic of meconium peritonitis?

DR SCHULZ I do not know anything else that causes areas of calcification over the surface of the peritoneum.

DR CASTLEMAN Neuhauser,⁵ at the Children's Hospital, has reported 3 cases with exactly this appearance.

Vomiting of a newborn infant in the first twenty-four hours of life is extremely rare. When it does occur, it suggests that the baby is seriously sick and deserves careful examination to find the cause. Certainly a flat plate of the abdomen should have been taken. One should also resort to the test introduced by Dr. Sidney Farber,¹—I blush to discuss this case with Dr. Farber in the audience,—which consists of examining the meconium to see if it contains cornified epithelial cells that the baby had ingested with the amniotic fluid. The presence of such cells in the meconium indicates that the intestinal tract is patent. If there are no such cells, the evidence is quite good that there is obstruction.

The baby's "stools became blue gray." Ladd and Gross² describe the stools in intestinal atresia as gray green. Throughout this history there is no indication whether the stools, which are mentioned at least twice, were small starvation stools, or whether they were large and contained milk curd. That information would be helpful to have.

Barium was given by mouth in the maternity hospital in an attempt to decide whether or not intestinal obstruction was present. In a newborn infant one does not have to resort to giving barium by mouth, and usually it is undesirable to do so. Certainly barium by mouth should not be given before a flat film of the abdomen is taken, and every effort should be made to make the diagnosis without giving barium.

Physical examination revealed a dehydrated youngster. Peristalsis was practically absent. As the child vomited fecal material, the intestinal obstruction would appear to have been fairly low.

DR. BENJAMIN CASTLEMAN: The record states that the baby vomited questionable fecal and bile-stained material. The stools were small and fecal.

DR. BUTLER: Then we are not so sure.

The next thing of note is the x-ray examination. I am sure that the films were taken immediately on admission to the hospital. There are two things of particular interest to look for in such patients: whether there is air in the peritoneal cavity and whether there are small areas of calcification. I wonder if we could see the x-ray films.

DR. MILFORD D. SCHULZ: You can see the barium in the stomach remaining from the examination done prior to admission to this hospital. The stomach is outlined by air, but if that air were free in the peritoneal cavity I believe that it would extend up over the liver, in other words, what is seen is probably air in the tremendously dilated loops of bowel. In the right lower quadrant is a large collection of barium that is obviously in a large dilated viscus. Here are tiny collections of opaque material plastered over the edge of the liver, along the peritoneal surface. They do not look like barium.

DR. BUTLER: I was going to ask whether the areas

of calcification appeared to be barium or the calcification that is seen in meconium peritonitis.

DR. SCHULZ: I should suspect the latter, if barium can get out of the bowel, air ought to be able to get out, and then if barium goes to the liver, air should also go there.

DR. BUTLER: So the x-ray films certainly confirm what is obvious from the story: namely, this patient had intestinal obstruction. Whether it was partial or complete remains to be seen. Furthermore, the x-ray studies suggest that this child had meconium peritonitis. It is too bad we do not have more information about the stools, both regarding the presence of cornified epithelial cells and the appearance of milk curds.

One might ask whether the intestinal obstruction was due to a congenital anomaly with atresia, to a congenital anomaly with stenosis or to meconium ileus. Dr. Farber³ has clearly described the obstruction due to meconium ileus and has correlated its occurrence with pancreatic achylia. Whatever the final picture, there was atresia of the bowel with obstruction. Whether it was congenital stenosis of the bowel with meconium or barium impacted above the obstruction or whether it was meconium ileus with pancreatic achylia does not at the moment affect the initial therapeutic procedure, which, of course, is operation. There are three things about the operation. First, the infant should have been operated on before the fifth day. Secondly, if atresia or stenosis is found, primary incision of that area and anastomosis, not enterostomy, is the procedure of choice, the reason being that in young infants atresia is frequently quite high in the gut and, if enterostomy is performed, one has a difficult time controlling nutrition and hydration. The third point concerns the use of pancreatic enzymes to dissolve the meconium, if at operation one finds meconium ileus on the basis of pancreatic achylia, in such cases there is an extremely tenacious meconium. I shall leave that aspect of the discussion to Dr. Farber.

My diagnosis in this case is intestinal obstruction, probably due either to stenosis or to atresia, aggravated by impaction of meconium and probably by some of the barium that was given and with meconium peritonitis and death before operation could be carried out.

CLINICAL DIAGNOSIS

Meconium peritonitis

DR. BUTLER'S DIAGNOSES

Intestinal obstruction due to congenital stenosis or atresia

Meconium peritonitis

directed toward the medical profession. An editorial in one of the newspapers stated that the physicians were less active, resourceful and persuasive than their opponents and that they did not make their strength felt fully, either as individuals or as a group. If this criticism is true, and there seems to be some justification for it, something surely should be done. Although there are certain explanations for this state of affairs, more true today than ever before because of the war, there can be no really legitimate excuse. The physician has sound knowledge in matters of this kind. Individually and as a group he must make himself heard and understood, particularly when the public welfare is at stake. This is a definite obligation.

The Chiropractic Bill remained in Governor Tobin's hands until July 20, when he returned it to the House with his veto attached. The following quotation from the Governor's veto message shows how clearly he understood the implications of this proposed law: "It would establish new and different standards of education and qualification for applicants seeking to practice in a field in which minimum standards are already established by statute. Thus it would introduce into the statutory system a double standard for the selection of practitioners in the field of medicine." It is to be hoped that when the Committee on Legislation submits its final report of the year, it will read into the record the Governor's veto message in its entirety.

For what was accomplished, due tribute should be paid to the Committee on Legislation of the Massachusetts Medical Society,—particularly to its tireless chairman, Dr. William E. Browne,—and to other members of the Society who gave generously of their time. The committee deserves well of the Society and what is still more important, it deserves well of the public at large.

CANINE

THE past prevalence of canine rabies, which flourished almost as a democratic institution in this Commonwealth until recent years, led to the adoption of certain standard practices. Chief among

these is the rule that any person bitten by an unidentified dog that escapes later detection must receive antirabic treatment. The more there are of unidentifiable dogs that roam our streets and byways, the oftener will it become necessary to invoke this rule of safety.

The incidence of dog rabies in Massachusetts, according to information furnished by the Commissioner of Public Health, has shown consistent improvement during the past dozen years, dropping from 331 cases in 1934 to 58 in 1938, to 20 in 1942, to 5 in 1943 and to 1 in 1944, with none, to date in 1945. The last case of human rabies occurred in 1935. The reason for this fall in incidence of dog rabies is not certain; it may have resulted from the preventive measures that have been adopted or it may simply reflect the natural rhythm in the rise and fall of the disease.

The history of rabies control in Massachusetts is of interest. Prior to 1934, it was attempted by area quarantine, but since the power of action is vested in the local communities and since there are over three hundred and fifty such political entities in the Commonwealth, concerted and co-operative action was never possible. In 1934 and subsequently, communities have been encouraged to organize dog-inoculation clinics, and perhaps because of the volume of such inoculations, it has been since 1934 that the decline in the disease rate has taken place. The present recommendation of the Department of Public Health is that communities in which cases of dog rabies have occurred, as well as contiguous communities, shall pass orders that no dogs be allowed on the streets, except on leash, unless they have been inoculated with antirabic vaccine within the previous year.

A considerable increase in the number of dogs untagged, uncollared and apparently unlicensed that are wandering in the streets of various municipalities of the Commonwealth has been noted. The stray dog is a potential health hazard, and in recognition of this fact the Commonwealth has for some time had a law requiring that all dogs be licensed and each community employ, under normal conditions, dog officers whose duty it is to apprehend, seize and dispose of unlicensed members of the canine family.

THE 1945 LEGISLATURE

JULY 25 brought to a close another chapter in the legislative history of the Commonwealth. In many respects this session of the General Court was an unusual one — extraordinary because of its length and even more extraordinary, from the physician's point of view, because of the time and attention that it gave to subjects pertaining to medical practice.

Many controversial subjects were discussed by this legislative body, none, however, were more so than those that concerned the laws regarding the practice of medicine in the Commonwealth. Reason had a hard time with emotion. Many times, confusion of the Legislature seemed to be the object

aimed at. So innumerable were the red herrings drawn across the trail, that the trail itself was often obscured. The opposition set its stage skillfully, probably too much so, for as the lawyers put it, the case appeared to be "overtried."

It is gratifying that the major assaults on the Medical Practice Act were repulsed. These ranged all the way from further postponement of the effective date of the Approving Authority to its elimination. Furthermore, an attempt was made to set up a separate board of chiropractic, presided over by chiropractors, who would pass on the qualifications of those who would practice chiropractic in this state. Although this bill made no direct attack on the Medical Practice Act, it actually constituted a greater threat than all the other bills put together. In 1915, the Supreme Court of Massachusetts, in the case of *Commonwealth v. J. O. Zimmerman*, declared that the practice of chiropractic was the practice of medicine. The passage of this bill would have established a double standard for such practice and would have opened the way for innumerable healing cults to seek like concessions.

These bills were heard for the most part by either the Committee on Public Health or the Committee on Education, the former bearing most of the burden. The Honorable Joseph F. Montminy, senator from Lowell, presided over the Committee on Public Health with patience and good sense. The several bills having to do with the Approving Authority were finally consolidated by the committee itself into Bill 1980, which specifically exempted Middlesex University School of Medicine from the jurisdiction of the Approving Authority until July, 1949. This was reported favorably by the committee, Senator Montminy and Representatives Cutler, Vaughan and Harrington dissenting. This bill was voted on by the House on June 5, and by a vote of 148 to 74 was referred to the next General Court.

In the light of this action by the Legislature, it is difficult to understand why, on July 9, the House passed the Chiropractic Bill by a vote of 104 to 72. Subsequently the Senate concurred.

Curiously enough, it was not the House or the Senate that bore the brunt of the criticism that followed the passage of the Chiropractic Bill. Such criticism, and there was a good deal of it, was largely

The Chemistry and Pharmacy of Vegetable Drugs By Noel L. Allport, F.I.C., research chemist, British Drug Houses, Limited 8°, cloth, 252 pp., illustrated Brooklyn Chemical Publishing Company, Incorporated, 1944 \$4.75

This elementary treatise on the vegetable drugs should be of service to students of pharmacy and pharmacists. The pictures of the raw plant material are particularly interesting. An extensive index is appended to the text.

Atlas of the Blood in Children By Kenneth D. Blackfan, M.D., and Louis K. Diamond, M.D., assistant professor of pediatrics, Harvard Medical School, and visiting physician and hematologist, Infants' and Children's Hospitals, Boston. With illustrations by C. Merrill Leister, M.D., associate pediatrician, St. Luke's Hospital, Bethlehem, and Allentown General Hospital, Allentown, Pennsylvania 4°, cloth, 320 pp., with 70 plates and 19 charts. New York: The Commonwealth Fund, 1944 \$12.00

This atlas contains seventy illustrations in color of blood cells seen in normal and in pathologic states in infancy and in childhood. It is based on the blood changes observed in more than five thousand infants and children at the Hematology Laboratory at the Infants' and Children's Hospitals, Boston, since 1927. This vast experience with diseases of the blood in children has been condensed in this unique atlas. Since practically all the diseases affecting the blood in adults also occur in children, the work should be useful to the general practitioner, as well as to the pediatrician. The color plates are excellent, the text is well printed, and a selected bibliography is appended to the text. The work is recommended for all medical libraries.

Pastoral Work and Personal Counseling By Russell L. Dicks 12°, cloth, 230 pp. New York: The Macmillan Company, 1944 \$2.00

Mr. Dicks is an authority on pastoral counseling and in this new work has covered the whole field in its many and varying aspects and especially in relation to other professions. There is much of medical interest throughout the text, especially in those chapters having to deal with pastoral calls on the sick, those contemplating marriage and war neurotics. The last chapter considers the relations of the clergyman and other professional workers, such as the physician, the nurse and the social worker.

The Avitaminoses: The chemical, clinical and pathological aspects of the vitamin deficiency diseases By Walter H. Eddy, Ph.D., and Gilbert Dalldorf, M.D., pathologist of the Grasslands and Northern Westchester hospitals, Westchester County, New York. Third edition 8°, cloth, 438 pp., with 38 tables, 46 figures and 47 plates. Baltimore: Williams and Wilkins Company, 1944 \$4.50

The first edition of this authoritative text was published in 1937, followed by a second edition of 1941, and the authors now find it necessary to publish a third edition. The text has been rearranged to sharpen the separation between the deficiency diseases and the chemical nature and functions of the vitamins. The book is divided into three parts: the vitamins, treating of their nature and their function, the avitaminoses, in which the deficiencies of the various vitamins are considered, and technical methods: vitamin assay and vitamin values. The chapters on the chemical nature of the vitamins and cellular oxidation have been rewritten and much new material has been added, including many illustrations.

The Story of a Hospital: The Neurological Institute of New York, 1909-1938 By Charles A. Elsberg, M.D., 12°, cloth 174 pp., with 34 illustrations. New York: Harper and Brothers, 1944 \$3.50

Dr. Elsberg has written interestingly of the founding of the Neurological Institute in New York and of all its developments to the year 1938. The author has been associated with the institution from its beginning when the idea of an institution entirely devoted to the study and treatment of diseases of the nervous system was new in this country. At first, the hospital was housed in a building with small and poorly arranged accommodations for patients and little space for laboratories, but nevertheless considerable clinical research was done in these inadequate quarters. The new hos-

pital building was first used in 1929, and in 1955 the Department of Child Neurology was founded. The tenth chapter enumerates the contributions of the Institute to progress in neurology. Appended to the text are lists of trustees from 1909 to 1938 and of physicians and surgeons for the same period. This small book constitutes an important contribution to the history of neurology in the United States.

The Abortion Problem: Proceedings of the conference held under the auspices of the National Committee on Maternal Health, Incorporated, at the New York Academy of Medicine, June 19 and 20, 1942 Howard C. Taylor, Jr., M.D., conference chairman 8°, cloth, 182 pp. Baltimore: Williams and Wilkins Company, 1944 \$2.50

Abortion is a major problem in medicine, public health and sociology. At the conference, held in 1942, many authorities discussed the subject in its various aspects. The text is divided into four parts: the magnitude of the abortion problem, including the frequency of abortion and its effects on the general health of the individual, spontaneous abortion and its prevention, social, moral and economic causes, and control of the abortion problem. The legal aspects are considered in the last part. This valuable reference source should be in all medical, public-health, sociologic and legal libraries.

Lead Poisoning By Abraham Cantarow, M.D., associate professor of medicine, Jefferson Medical College, assistant physician, Jefferson Hospital, and biochemist, Jefferson Hospital, Philadelphia, and Max Trumper, Ph.D., lieutenant commander H-A(S), U.S.N.R., Naval Medical Research Institute, Bethesda, Maryland, and consultant in industrial toxicology, Cynwyd, Pennsylvania 8°, cloth, 264 pp., with 5 illustrations and 21 tables. Baltimore: Williams and Wilkins Company, 1944 \$3.00

Lead poisoning is probably one of the most important of the toxic hazards encountered in modern industry. Prior to World War II, about 750,000 tons of lead were annually produced and consumed in the United States and in 1940 about 54 per cent of the industrial plants in fifteen states were handling lead or its compounds. The physiology, pathology and clinical manifestations of lead are considered at length. There are special chapters on lead in the blood, body fluids and excretions, procedures for the determination of lead and the normal intake of lead. There is also a short chapter on the occurrence of chronic lead poisoning in industry. An extensive, selective bibliography is appended to the text. This comprehensive reference text should be in all medical and public-health libraries, as well as on the shelves of industrial physicians.

The Etiology, Diagnosis and Treatment of Amebiasis By Charles F. Craig, M.D. 8°, cloth 332 pp., with 45 illustrations and 10 tables. Baltimore: Williams and Wilkins Company, 1944 \$4.50

Dr. Craig in this new book has tried to include all the important data accumulated during the period since the publication of his earlier work in 1934. The book is well printed on good paper, and a selected list of references follows the text.

The Eclipse of a Mind By Alonzo Graves, M.D. 8°, cloth, 722 pp. New York: The Medical Journal Press, 1942 \$5.00

Autobiographies of sick persons, especially those afflicted with mental disorders, are of interest and value in the study of disease. This book records the life history of an extremely intelligent individual who throughout life had been afflicted with manic-depressive psychosis, having gone through eight attacks, five of which required complete hospitalization. Interspersed with the author's text are the hospital records of admission and discharge and also comments of the various physicians having charge of the patient. A unique feature of the presentation is the placing side by side, of hospital records of the patient's behavior and his explanations and elaboration of the same on recovery. The biography was written by the patient at the suggestion of the attending physician during the fourth hospitalization, and on the basis of the material obtained the evident gaps were filled in by replies to a series of questions. The patient recovered after

Dog rabies may never again become prevalent in this country, but if there is any circumstance that will favor its spread and make human antirabic treatments necessary it will be that of allowing unidentified dogs on the streets, and if there is any circumstance that will form a basis for control it will be the registration of all respectable canines, together with the disposal of all others

MEDICOLEGAL ABSTRACT

Liability for Malpractice X-ray treatment of pilonidal cyst, liability of an x-ray assistant
Two recent New Jersey decisions arose out of the same situation. The patient brought separate suits against Dr S and Dr C for alleged malpractice.

The jury found against Dr S. The patient introduced testimony having to do with x-ray therapy by witnesses who were licensed physicians but who did not hold themselves out as specialists in that branch of the profession. The court held that "having qualified as medical doctors, they [the physicians] are competent to testify on all medical subjects upon which they claim sufficient ability to express an opinion," so that the defendant could not exclude such testimony but only attempt to disclose by cross-examination that the witnesses did not possess sufficient knowledge.

The court held that the failure of Dr S's treatment might be evidence of his negligence. The trial judge had refused to charge that "the mere fact that treatment given in any case does not result satisfactorily or beneficially to the patient is not evidence of negligence." In sustaining the trial judge the court said:

The fact of nonbeneficial result may or may not be evidence of negligence. If despite proper diagnosis and treatment no benefit resulted no negligence could be charged, but if the treatment failed because of failure to exercise reasonable diligence, knowledge or skill, the result may be evidential of negligence.

The court, however, quoted with approval an earlier New Jersey decision as follows:

The physician in attending his patients, engages that he will use due care to discover the nature of the disease which gives occasion for his services, and in applying the usual remedies, but beyond this measure of skill and diligence the law makes no exaction. If he is to be held for results, or as a guarantor of success, it can be only in virtue of his express agreement.

The basis of the jury's verdict against Dr S was apparently either that he had given x-ray treatments for a condition that he had correctly diagnosed as a pilonidal cyst or that he had erroneously diagnosed as a furunculosis and that an excessive dosage of x-ray had been given.

The trial judge decided in favor of Dr C without

letting the case against him go to the jury, and the court sustained the trial judge. Under the court's view of the case the question was whether, on the evidence introduced by the patient, the jury could reasonably conclude that Dr C and Dr S were associates and engaged in a joint enterprise, so that each would be liable, and on that view the case is an interesting one on the existence of such a relation.

The patient's testimony was that he made an appointment to meet Dr S at his office and had never seen or heard of Dr C until he met him at Dr S's office. Dr S examined him with Dr C present but merely looking on. Dr S diagnosed the case and prescribed the quantity and frequency of x-ray treatment and administered all the six treatments given except the third and fourth. In the third and fourth Dr C handled the application to and removal from the patient's back of the machine. Arrangements concerning the amount of fees were made by the patient with Dr S, and all bills for services were payable to Dr S, made out on his billheads and paid by the patient to him or his secretary. There was no testimony that Dr C received any part of the fees paid by the patient to Dr S, or any proof of any advertisement that Dr C and Dr S held themselves out as associates, or any proof that Dr C in any way undertook to direct the treatment to be given the patient. Dr C merely continued the same treatment that had been prescribed and given by Dr S. The court held from these facts that it could not reasonably be concluded that Dr S and Dr C were associates and engaged in a joint enterprise in the care of the patient.

The language of the decision is guarded and leaves room for the possibility that if the question had been properly raised the evidence might have been sufficient to show a relation between Dr C and the patient by reason of which Dr C would have been liable for any negligence of his own — (*Young v Stevens*, 132 New Jersey Law 124, 39 Ail 2d 115 [1944], *Young v Crescente*, 132 New Jersey Law 223, 39 Ail 2nd 449 [1944]).

THE RELATION BETWEEN VAGAL ACTIVITY AND AURICULAR FIBRILLATION IN VARIOUS CLINICAL CONDITIONS*

MARK D. ALTSCHULE, M.D.†

BOSTON

AURICULAR fibrillation is frequent in various forms of heart disease and in thyrotoxicosis, and its occurrence in other conditions is also recognized.¹ Although this arrhythmia is often encountered in clinical practice, its origin is not understood by most clinicians, in spite of the fact that it has been the subject of considerable fruitful study.

The available reports of studies in animals in which auricular fibrillation was regularly produced definitely establish the fact that vagal activity is one of the factors responsible for its occurrence.² The earlier studies on animals were not entirely satisfactory from a clinical point of view, since in all cases the experiments were performed under anesthesia, with the chest open and usually with electrodes and recording devices attached directly to the heart. It was therefore believed that similar experiments on normal, intact, unanesthetized animals might approach clinical conditions in man. Accordingly, the effect of the injection of acetyl- β -methyl choline, a substance closely related to the vagus hormone, was studied in one hundred experiments on 10 intact, unanesthetized dogs.² The drug was given intravenously in doses of 0.5 to 2.0 mg. In 3 dogs the only arrhythmia produced was partial heart block, whereas in the other 7 either auricular fibrillation or partial heart block occurred. In the latter group of animals it was impossible to predict which of the two arrhythmias would occur, since consecutive injections of the same dose of the drug might produce either. The heart block that occurred was characterized by the regular or irregular dropping of ventricular beats, whereas the P-R interval showed little change. No fatalities occurred during any of these studies, and one of the animals remained alive and well several years after having been subjected to these experiments. The animals that developed marked bradycardia resulting from heart block also exhibited Adams-Stokes

phenomena, recovery in every case occurred spontaneously. As a result of these studies it was considered to have been demonstrated that auricular fibrillation can be produced in intact animals by vagal hyperactivity. The alternative occurrence of auricular fibrillation or partial heart block was considered of great significance, and is discussed below.

Nahum and Hoff³ have shown that the intramuscular injection of acetyl- β -methyl choline in patients with thyrotoxicosis and a regular rhythm results in the development of transitory auricular fibrillation. Battro and Lanari^{4, 5} also produced auricular fibrillation in normal human subjects by means of the intracarotid injection of acetyl choline. In the present study, however, the use of these substances to attempt to induce auricular fibrillation in patients with heart disease and regular rhythm was considered too drastic a procedure and was not attempted. Accordingly, other studies on the relation between vagal activity and auricular fibrillation in man were undertaken.

It has been shown by Bruenn⁶ and by Keith⁷ that prolongation of the P-R interval in rheumatic heart disease is almost always due to vagal activity. A study was therefore made of the occurrence of auricular fibrillation in patients with this vagal arrhythmia.⁸ A high degree of correlation between the occurrence of partial heart block and auricular fibrillation in rheumatic heart disease was found. In 55 consecutive cases of a prolonged P-R interval, — transitory in 10 children and persistent for one month to eight years in the remainder, — 21 patients developed auricular fibrillation. Analysis of the sequence of electrocardiographic changes in the cases studied most thoroughly, such as the one covered by Table 1, showed that, initially, auricular fibrillation and low-grade heart block occurred alternately, with occasional periods of a normal P-R interval as well. If allowance is made for the fact that acetyl- β -methyl choline induces heart block, characterized in dogs by regularly or irregularly dropped beats, and in man by prolongation of the

*From the Medical Service and Medical Research Laboratories, Beth Israel Hospital, and the Department of Medicine, Harvard Medical School.
†Associate in Medicine, Harvard Medical School; associate visiting physician and research associate, Beth Israel Hospital.

the fifth hospitalization and did not return for further treatment. The work is divided into three parts. The first deals with heredity and environment, marriage and consequences, and psychiatric interludes. Part two relates the story of seven attacks and four hospitalizations. The third part contains the author's reflections on his personality, including his sex life and his dream life, and his comments on mania and depression. The final chapter tells the story of the fifth hospitalization, the final attack before the patient's return to civil life. The story is written in a pleasing, narrative style and printed in good type on good paper. Such biographies are uncommon and should prove of exceptional value to psychiatrists and allied scientists and to human biologists. The book is recommended for medical libraries.

Interns Handbook A guide, especially in emergencies, for the intern and the physician in general practice. Prepared by members of the faculty of the College of Medicine, Syracuse University, under the direction of the Publication Committee, M S Dooley, M D, professor of pharmacology, and Maynard E. Holmes, M D, professor of clinical medicine, co-chairmen. Third edition. 16^o, cloth, 579 pp, with 15 tables and 15 figures. Philadelphia: J B Lippincott Company, 1944. \$3.00.

This handy manual, first published in 1929 and appearing in a second edition in 1938, has been thoroughly revised and should prove useful as a handbook of ready reference. The sections on chemotherapy, endocrine disturbances and the vitamins have been entirely rewritten. The subjects of pulmonary emboli and the vitamins are included for the first time. The text is divided into three parts: medicine, surgery and therapy. The therapeutic part includes a long list of well known drugs, with their therapeutic indications.

Beloved Crusader, Lawrence F Flick, Physician. By Ella M E Flick. 8^o, cloth, 390 pp, illustrated. Philadelphia: Dorrance and Company, 1944. \$3.50.

Dr Flick was a pioneer in the campaign against tuberculosis in the United States. He was a strong individual and as a crusader in this field naturally made many enemies, as well as friends. He was instrumental in founding the White Haven Sanatorium and the Phipps Institute in Philadelphia. He was responsible for bringing the international conference on tuberculosis to the United States in 1908. He was also active in congresses in foreign countries. In 1907 he made a trip as a delegate to the fourteenth International Conference of Hygiene held in Berlin, and it was at that time that he succeeded in obtaining the international congress for Philadelphia, for which Mr Henry Phipps guaranteed five thousand dollars for expenses. In 1909 Dr Flick traveled to Europe to study tuberculosis, and his diary of this trip comprises a chapter in the book. Dr Flick was greatly interested in history, and in 1884 he took a large part in organizing the American Catholic Historical Society of Philadelphia. This biography by his daughter is a worth-while contribution to the history of tuberculosis in the United States and the live factual story of a great man.

Sickness Indemnification. A panel discussion by R A Hohaus and others. Transactions Series, Bulletin No 1. 55 pp, 8^o, paper. Pittsburgh: Industrial Hygiene Foundation, 1944. Price on request.

This is a discussion on what is commonly known as health insurance. Three participating experts and the chairman dealt with the economic and administrative problems of group-health programs to employees and their families. Andrew T Court discusses the economic basis of health, in which he compares occupational and nonoccupational disability, bringing out the fact that disability from occupational causes is low and is being reduced, whereas nonoccupational disability has shown no improvement. Various interesting charts show how the increase of income above budget needs does not seem to improve health, death-rate trends indicate improvement in health of moderate-income groups. Increase of income above budget needs increases medical care moderately but inflates medical expenses. Short waiting periods result in increased sick claims of long duration, and the nursing of minor indisposition does not reduce serious sickness. Dr Gafaer discusses sickness indemnification and gives in

detail the experience of sick-benefit organizations connected with two public utilities and two iron and steel companies. There is also given in detail the data concerning sick-benefit organizations of eleven member companies of the industrial hygiene foundations.

Putting the Disabled Veteran Back to Work, II. A further panel discussion by C D Selby, M D, and others. Special Series, Bulletin No 3. 33 pp, 8^o, paper. Pittsburgh: Industrial Hygiene Foundation, 1944. Price on request.

This short pamphlet considers in order the following subjects: readjusting the veteran, vocational rehabilitation and placement of the veteran, new experiences in putting the disabled veteran back to work, and job-placement qualifications and guidance to disabled veterans returning to work. This timely pamphlet, as well as the preceding one, should prove useful to all physicians and others having to do with personnel in industry.

Fischerisms, Being a Sheaf of Sundry and Divers Utterances Culled from the Lectures of Martin H Fischer, Professor of Physiology in the University of Cincinnati. By Ray Marr. Third and enlarged edition. 24^o, cloth, 83 pp, with a frontispiece. Springfield, Illinois: Charles C Thomas, 1944. \$1.80.

The aphorisms of Professor Martin H Fischer, professor of physiology at the University of Cincinnati, were first published in 1930, and a later edition appeared in 1937. The third edition has been enlarged, by Ray Marr, by the addition of many new sayings added during the past seven years. The terse pithy statements collected in this volume were uttered by Professor Fischer during his lectures on physiology. They were collected mostly from the margins of the notebooks of students. This small volume is a welcomed addition to the collections of aphorisms of Osler and others. The volume is not for general circulation, having been privately printed for the students of Professor Fischer.

Personal Mental Hygiene. By Dom T V Moore, O S B, M D, Ph D, professor of psychology and psychiatry, Catholic University of America. 8^o, cloth, 331 pp. New York: Grune and Stratton, 1944. \$4.00.

This book is intended primarily for the individual, and because of this objective, the workings of the mind and its adjustments to life have been illustrated by an analysis not only of clinical material but also of various historical and literary personalities. The author points out the possibilities of ordinary emotional adjustment and at the same time brings into psychiatry the higher things of human life. It is an attempt to familiarize the individual with the possibility of emotional adjustment to the difficulties of life and also by a number of examples to provide a knowledge of wholesome attitudes of mind, ideas and principles.

The Marihuana Problem in the City of New York. Sociological, medical, psychological and pharmacological studies. By the Mayor's Committee on Marihuana. 8^o, cloth, 220 pp, with 53 tables. Lancaster, Pennsylvania: The Jaques Cattell Press, 1944. \$2.50.

This comprehensive study of a public-health problem was made by a special committee of the New York Academy of Medicine. All aspects of the drug are covered. A short historical sketch of the growth and usage of the drug, including the pertinent facts concerning hashish, precedes the text.

FIBRIN FOAM AS A HEMOSTATIC AGENT IN SUPRAPUBIC PROSTATECTOMY*

WILLIAM C. QUINBY, M.D.,† AND ERNEST K. LANDSTEINER, M.D.‡

BOSTON

OF THE many problems presented by the operation of prostatectomy none are of more importance than that of the adequate control of bleeding from the prostatic cavity after the gland has been enucleated. Whether the prostate is approached through the urethra, by way of the perineum or by the suprapubic route, this problem remains of equal importance and difficulty. The literature of prostatic surgery abounds with many methods and devices for hemostasis that need no elaboration. In general at the present such devices consist of one sort or another of catheters and elastic dilatable bags, which after distention with fluid can be drawn down into the prostatic cavity and thus lessen the bleeding by pressure. Although these appliances are of considerable value, none are perfect, and the discomfort to the patient attendant on them is always an undesirable factor. Furthermore, the use of devices for hemostasis that must subsequently be removed contradicts the general surgical maxim that all bleeding should be adequately controlled before the wound is closed.

With the production of so-called "fibrin foam" by the Plasma Fractionation Laboratory of the Harvard Medical School,§ the opportunity arose to use this substance in the cavity left by removal of the prostate, as a new method of promoting complete

hemostasis, based on a sound physiologic principle. It seemed wise at the beginning to confine our observations entirely to the operation of prostatectomy by the suprapubic route in a single-stage procedure. The foam was used in pieces of convenient size that had previously been soaked in a solution of thrombin. It was held in place on the bleeding surface by a pledget of gauze over which negative pressure was made by suction through a tube. Four to six minutes of such pressure was sufficient to produce clotting and adhesion of the foam. On the advent of a satisfactorily dry prostatic bed,—on the average in ten to twenty minutes,—the bladder was closed by suture, leaving a mushroom catheter of small size (No. 18 Fr.) in the upper angle of the wound, so adjusted that the intravesical head of the catheter lay so far as possible from the area of operation. No other hemostatic agent was used, although in one case two rather large "spurters" were controlled by a stitch before the foam was put in place. In all cases, control of the bleeding by the foam was entirely adequate, much better than when pressure by bag was used, and in no case was there secondary bleeding.

Twelve patients form the basis of the present report of our experience with this substance thus far. The average age was sixty-nine years, and the average weight of the removed prostate 39 gm. The shortest time after operation in which the urine became clear on visual inspection was one day (2 cases), and the longest, six days (3 cases), in the remaining 7 cases the urine cleared in two or three days. The suprapubic catheter was removed in three to seven days, and the average time in which the wound healed and became dry was fifteen and a half days, the shortest period being eleven days and the longest twenty-four days.

series of injections of acetyl- β -methyl choline. Both these reactions appear to be due to vagal action.

A similar study in patients with paroxysmal auricular fibrillation following myocardial infarction was made.¹⁰ Here again, a high degree of correlation between the occurrence of a prolonged PR interval and of auricular fibrillation was found, 9 of 14 cases with paroxysmal auricular fibrillation having a prolonged P-R interval as well. As yet, evidence proving the vagal origin of the changes in the PR interval in this condition is fragmentary, but in several cases studied atropine has been shown to abolish them. In single cases, such as the one shown in Table 2, the sequence of events was similar to

that in the rheumatic subjects and in the dogs receiving acetyl- β -methyl choline that is, auricular fibrillation and partial heart block occurred alternately. A more recent study by Derow and Wolff¹¹ has shown that this relation between vagal hyperactivity and auricular fibrillation is also present in elderly patients with chronic coronary arterial disease. These authors also showed that in addition to partial heart block, sinus bradycardia may occur

at one time or another in patients who develop auricular fibrillation.

Reference has already been made to the work of Nahum and Hoff,³ which established the importance of vagal activity in precipitating auricular fibrillation in patients with thyrotoxicosis. Additional evidence of this connection is offered by the occasional occurrence of paroxysms of a prolonged PR interval alternating with those of auricular fibrillation in patients with hyperthyroidism. Two such cases with no evidence of organic heart disease have been observed in this clinic (Table 3).

Mines,¹² in his original work on circus movement in the heart, defined the conditions necessary for the development of auricular fibrillation as a shortened

refractory period and prolonged conduction time of the auricular myocardium. Stimulation of the vagus nerve shortens the refractory period of auricular muscle¹³⁻¹⁶ and thereby favors the occurrence of fibrillation. It is not unlikely, as Nahum and Hoff³ have suggested, that local inflammatory or metabolic changes in the auricle reinforce the tendency toward the occurrence of this, arrhythmia, which is initiated by vagal hyperactivity.

The source of the vagal impulses that give rise to prolongation of the PR interval and to auricular fibrillation in heart disease and thyrotoxicosis is obscure. It has been shown that vagal impulses that affect the heart reflexly may arise from the root of the aorta,¹⁷ the auricles of great veins¹⁸ and the lungs,^{19, 20} all of which may be involved in rheumatic inflammatory processes. In addition, congestive failure, by raising the auricular or venous pressure and causing pulmonary congestion, may also be a factor. These considerations do not, however, elucidate the origin of the vagal impulses causing cardiac arrhythmias in all cases of heart disease and in many cases of thyrotoxicosis.

SUMMARY

Evidence is presented that auricular fibrillation in certain types of heart disease and in thyrotoxicosis is a consequence of vagal activity. The origin of the vagal impulses that act reflexly on the heart to cause this arrhythmia is obscure.

difficult to use pieces of such grafts as so-called "postage-stamp" grafts Webster² has recently shown that phlo film may be used as a backing for

FIGURE 4 Recipient Site Ready for Grafting

grafts, and Evans³ has suggested cellophane for the same purpose

Before cutting a graft with a backing the drum is coated with dermatome cement and the backing film cemented to the drum as smoothly as possible. New coats of cement are then applied to the film and to the donor site and the graft cut as described by Padgett. The graft with its backing is removed from the drum and is placed on the recipient site. The backing prevents the normal contraction of the cut skin that results from its elasticity, and gives it added strength. The handling of the cut skin is consequently much easier, and any cutting of pieces to fit small or irregular areas is much more easily performed. Of more importance, how-

FIGURE 5 Graft in Place
Note the absence of sutures

ever, is the fact that no sutures are needed to maintain the graft at its original size and tension. The graft is maintained in place by even elastic pressure provided by a suitable pressure dressing, with or

without external splinting. The backing is easily peeled off after the graft has healed.

Experience with cellophane as a backing material has shown that it is very difficult to apply it to the dermatome without wrinkling. Even extremely small wrinkles cause irregularity in the thickness of the graft. A more serious difficulty is due to the relative stiffness of the cellophane and the graft. When attempts are made to fit the cellophane-backed graft to surfaces that are convex, concave, or irregular, wrinkling frequently results. This may result in the development of areas in which serum or blood collects beneath the graft because of poor approximation to the granulations, and over these areas the graft may be lost.

For some months, a fine-gauge nylon cloth* has been used for dressing the donor sites at skin-grafting operations in this hospital. A trial of this cloth in place of cellophane for skin-graft backing showed that it has qualities that made it desirable for this purpose. In the first place, it never wrinkles on the dermatome drum. Secondly, it sterilizes as

FIGURE 6 Graft at the Time of the Second Postoperative Dressing
Note the excellent "take"

easily as any textile and does not need special packing in the sterilizer to prevent adjacent surfaces from becoming adherent, as does cellophane. It is physically unchanged after sterilization. In spite of its relative limpness before being attached to the skin, it prevents contraction of the graft as well as does cellophane or sutures. Grafts backed with nylon conform better to irregular surfaces than do those backed with cellophane. In addition, it has been found possible to cut the skin 0.2 mm thick. Such grafts are slightly thinner than those that can be successfully cut and handled without backing. The donor sites from which such thin grafts have been taken heal quite rapidly and can

*This is the 1½-ounce nylon cloth used for parachutes. It is not over 0.1 mm thick and has a strength of 50 pounds per square inch in each direction. The warp is made of 40 Denier threads, one hundred and seven threads to the inch, and the weft of 60 Denier threads, seventy-eight to the inch. It was obtained from Textron Incorporated, Lowell, Massachusetts.

If spontaneous urination seemed a bit delayed, patency of the urethra was assured by the single passage of a sound of moderate size. Apparently the coagulated foam is not soluble in urine but after three or four days becomes disintegrated into a crumbling granular form, which passes easily through the urethra on urination. Postoperative irrigation of the bladder through the suprapubic catheter to remove small clots was carried out three times daily in the earlier cases, but with increased familiarity in the use of the foam it was possible in the last 3 cases to omit it.

There can be no doubt that by the use of foam as a

hemostatic agent in the operation of suprapubic prostatectomy the amount of blood lost is sharply diminished, the postoperative discomfort is lessened, the incidence of infection of the bladder is minimized, and the hospital stay is shortened.

SUMMARY

The use of fibrin foam as a hemostatic agent following suprapubic prostatectomy is described.

Because of the excellent results obtained in 12 cases, this means of controlling postoperative hemorrhage appears preferable to any method previously employed.

CLINICAL NOTES

NYLON BACKING FOR DERMATOME GRAFTS*

ROSS W. GREEN, M.D.,†
STANLEY M. LEVENSON, M.D.,‡
AND CHARLES C. LUND, M.D.§

BOSTON

EXPERIENCE with many skin-grafting operations in the repair of burn wounds of all sizes has shown that the Padgett dermatome technique gives extremely satisfactory results but is time-

the periphery of the graft. Frequently the suturing is the lengthiest part of the operation and thereby

FIGURE 2 Graft Being Cut from the Donor Site

increases the seriousness of the procedure. In addition, considerable care must be taken in the

FIGURE 1 Nylon Cemented to the Drum

consuming. To secure properly stretched grafts in place it is necessary to place many sutures at

drug, he was taking 120 mg daily, by the end of the 3rd year 150 mg, by the end of the 4th year 180 mg, and by the end of the 5th year 250 mg. He obtained prescriptions for the drug by consulting several physicians who did not realize that he had become an addict. He continued the use of the drug until the day of admission.

During the 5 years of addiction to amphetamine sulfate, the patient was able to work daily as a guard in a war plant, did some law practice in the evenings, and ate and slept well. Four months before admission he began to show mental symptoms in the form of sleeplessness at night and restlessness at work. He soon began to complain that searchlights were being thrown into his bedroom and felt sure that his home was being watched. Two weeks later he complained to his wife that his car was being followed when he was traveling to and from work — at first by one automobile but soon by at least six cars. This feeling was so real that he drove his car by devious routes to elude his pursuers, but without success. Finally he became so fearful that he left his job. On two occasions he asked the police to investigate prowlers about his home. One month before admission, he began to hear the voice of his son, who was in the armed forces in Europe. He interpreted the stars in the sky as signal lights coming from his son, who he thought was flying in an invisible helicopter. He would spend hours in the evenings looking at the sky and conversing with his son, and expected that the latter would visit him at any moment. On one occasion he prepared a meal for the boy and his commanding officer and waited for them for hours. In an effort to explain his experiences, he developed the theory that he was being tested by the Government for an important secret-service position. Finally he became so hyperactive, sleepless and fearful that hospitalization was advised. He had lost 20 pounds in weight during the 5 months prior to admission.

The physical examination on admission was essentially negative. The weight was 172 pounds and the blood pressure 140/90. The heart and lungs were normal. Neurologic examination was negative and the blood picture was normal. A blood Hinton reaction was negative.

Mentally the patient was oriented in all spheres but had to insight into his condition and violently protested against what he felt was illegal commitment. He freely admitted having seen and heard his son outside his home and the admitting office. He remained excited, agitated, resistive, hallucinated and deluded, and refused food for 6 days. He required sedation for sleep. On the 7th day, he became more co-operative and took food, but stated that he could still see his son's airplane in the sky. He argued that since it would be possible for his son to be in a plane in this neighborhood, it would therefore be possible to see him, and that thus his experiences were not necessarily hallucinations. He frequently demanded that his wife engage an attorney and obtain his immediate release. He gradually became more and more co-operative and friendly, sought frequent interviews with the physicians, and in a short time readily accepted the fact that his unusual experiences were the result of his long-standing addiction. He still expressed the belief, however, that some of his experiences were real.

Three weeks after admission, he admitted that at night he looked at the sky with the hope that he would see some signal from his son's airplane. At that time he tended to be slightly euphoric, readily boasting about his past experiences with women and alcohol and admitting that he had been addicted to alcohol for years and had exchanged the liquor for amphetamine sulfate. He evidenced no real insight into his condition and insisted that hospitalization was no longer necessary to cure him of his addiction. He had no conception of the underlying personality deviations that early in life had led to his behavior pattern.

By the 4th week in the hospital, he had developed good insight into his past experiences, and had also begun to realize that he would be benefited by psychiatric guidance after leaving the hospital. He had gained 7 pounds in weight.

On the 30th day, the patient was discharged as recovered, the diagnosis being "psychosis due to drugs and other exogenous toxins (amphetamine sulfate)."

This case of acute hallucinosis in an amphetamine sulfate addict is of special interest because the patient was able to ingest extremely large doses of the drug over a long period of time without suffering any apparent physical ill effects. After almost five years of addiction, mental symptoms developed. There was no loss of weight until the mental symptoms appeared, and no rise in blood pressure was noted. This addiction occurred in a man who had previously been addicted to alcohol and who had shown many neurotic traits.

From an analytical viewpoint, the alcoholic addict and the drug addict present many psychogenic factors occurring early in life, arresting emotional development at the oral erotic stage. Childhood frustrations and loss of mother love, bringing with them feelings of insecurity and inferiority, are well recognized factors in the production of alcoholic addiction. The childhood of this patient was unhappy, with considerable emotional trauma from the time of his mother's death to adolescence. His excessive smoking, love of sweets, drinking, early sex experiences, choice of profession, talkativeness and, finally, drug addiction are all a part of an oral erotic pattern of behavior. The acute mental symptoms presented closely resembled those seen in acute alcoholic psychoses. The visual hallucinations were the most prominent ones. With the disappearance of these experiences, the patient showed no evidence of the depression that usually follows in alcoholic psychosis.

This case strongly confirms the conclusions of Reifenstein and Davidoff⁷ that psychoneurotic patients and alcoholic addicts are prone to become addicted to the use of amphetamine sulfate. The use of the drug in the treatment of alcoholic addiction should be limited to hospitalized cases.

SUMMARY

A case of acute hallucinosis in a patient who was addicted to amphetamine (Benzedrine) sulfate and formerly to alcohol is presented and discussed.

be used again in a relatively short time. On all areas where split-thickness grafts are indicated, grafts of this thickness have given satisfactory end results.

The following case illustrates the use of this technic.

M P, an 11-year-old boy, was admitted on November 18, 1944, shortly after receiving flame burns of the entire lower right leg, the total third-degree area being 6 per cent. The surface treatment on entry consisted in the application of a dry, sterile pressure dressing without preliminary cleansing. These dressings were freshly applied every 2 weeks. On the 59th day, two dermatome drums of nylon cemented grafts were removed from the abdomen and left thigh and applied to the granulating areas. A firm pressure dressing with a plaster cast was applied. On the 7th postoperative day, the dressings were removed. The "take" of the graft was found to be excellent. Figures 1-6 illustrate the operative technic used.

SUMMARY

A technic employing nylon for the backing of dermatome grafts is described.

ACUTE HALLUCINOSIS AS A COMPLICATION OF ADDICTION TO AMPHETAMINE SULFATE

REPORT OF A CASE

JACOB NORMAN, M.D.,* AND JOHN T. SHEA, M.D.†

FOXBOROUGH, MASSACHUSETTS

AMPHETAMINE (Benzedrine) sulfate has been widely used in recent years in the treatment of chronic alcoholism,¹ with or without psychosis of narcolepsy and of depression, because of its stimulating action on the central nervous system. Its therapeutic action is to enhance mental activity and increase ability to concentrate; it lessens the feeling of fatigue and elevates the mood.

The toxic effect of amphetamine sulfate varies a great deal in different persons.² Small doses may produce alarming symptoms, whereas it is reported that large doses taken over a period of years for narcolepsy have produced no apparent ill effects.

Apfelberg³ reported the case of a man who remained in coma for thirty-six hours after taking 140 mg. of amphetamine sulfate. Two fatal cases have been reported in the literature^{4, 5}—one was that of a 25-year-old student who collapsed and died after taking 30 mg. of the drug daily for a few days, and the other that of a child of one year who died after the accidental ingestion of 40 mg.

Goodman and Gilman⁶ state that the most frequent toxic effects are restlessness, insomnia, talka-

tiveness, irritability, confusion, hallucinations and delusions.

Reifenstein and Davidoff⁷ reported a series of cases of alcoholic psychosis treated successfully with amphetamine sulfate. Miller⁸ gave the drug to a large group of patients with chronic alcoholism without apparent ill effects or addiction. Reifenstein and Davidoff strongly advise that the drug be limited to institutionalized cases, because of its tendency to produce addiction and the relatively frequent and unpredictable occurrences of serious toxic reactions. They have observed that there is a tendency toward addiction to amphetamine sulfate in neurotic patients and in those addicted to alcohol, morphine and cocaine.

CASE REPORT

A B (F S H), a 49-year-old lawyer of Irish descent, was admitted to the Foxboro State Hospital on February 10, 1945, with somatic, visual and auditory hallucinations of 4 months' duration. He was hyperactive, suspicious and belligerent. He admitted having taken amphetamine sulfate in steadily increasing doses for the last 5 years, and had reached a maximum daily dosage of 250 mg.

The patient's mother died of tuberculosis when he was 2 years of age. The father was an alcoholic addict and died at 60. An older brother died of tuberculosis, and a sister met accidental death at 27. The patient was reared by a childless aunt, who demanded rigid discipline.

The patient's birth was normal, and he had the usual childhood diseases. His progress in school was average, and at the end of the 2nd year of high school, at the age of 16, he left of his own volition, taking a job as a grocery clerk. Five years later he resumed his studies, attending night school, and later received his high-school diploma. He then studied law for 4 years and passed the bar examinations. He was well liked, made friends readily, was successful in his practice, and became quite active in local and state politics. Circumcision was performed at 12 years of age and appendectomy in 1933.

At the age of 12, the patient had his first heterosexual experience, following which he developed a penile infection and was circumcised. Between the ages of 17 and 25 he had frequent sexual experiences with various married women, toward whom he formed no emotional attachments. He married at 25 years and made a fairly good sexual adjustment. He had 2 children, a son of 23 and a daughter of 13. He admitted occasional extramarital relations, about which he felt no guilt. During the period of addiction to amphetamine sulfate his sexual desires and potency were increased.

The patient had been a heavy smoker since an early age, consuming thirty to forty cigarettes a day. For years he had been excessively fond of sweets. He began to use alcoholic beverages at the age of 17. At first he drank only on week ends, but the habit soon became a daily one. When he took up the study of law, he ceased drinking, abstaining completely for 5 years, but as soon as he began practice he resumed his drinking habits and continued to drink steadily for 7 years. After 5 years of successful practice of law, he met with severe financial reverses, owing to the economic crisis prevailing at that time, to speculation and to loss of clients on account of his alcoholic habits. After struggling for 2 years he gave up his law office and political and social activities and accepted employment on a WPA project. During the latter part of his heavy drinking periods the patient was frequently intoxicated and was twice arrested for driving under the influence of liquor, but at no time did he develop any symptoms of alcoholic psychosis.

In 1939 the patient consulted a physician because of fatigue and vague gastrointestinal symptoms, which he described as "an all-gone feeling." Amphetamine sulfate was prescribed, 10 mg. four times daily. The effect of the drug was so stimulating that he gave up the use of alcohol and did not return to it. He continued to take amphetamine sulfate, but gradually increased the daily dosage without the consent of his physician. By the end of the 2nd year of use of this

†Assistant superintendent, Foxborough State Hospital.

Rorschach method, and situational factors that might have produced or aggravated psychoneurotic symptoms. In patients with localized headache, these symptoms appeared to be more closely related to brain damage than to psychologic factors. Studies of postural vascular responses indicated no effects in patients with head injury different from those in psychoneurotic patients or in those convalescing from other illnesses. A follow-up study of 82 patients previously treated at the Montreal Neurological Institute showed that the long-term results with spinal or cranial subdural insufflation have been no better than those following pneumoencephalography, and that for none of these patients could the influence of other factors be ruled out. The authors emphasize the relation between psychologic and physical factors in the production of the symptoms after head injury and the need of considering the person as a whole in the prevention and cure of post-traumatic symptoms.

The factors influencing the development of the post-traumatic syndrome are discussed in a series of papers from the Boston City Hospital where 200 patients were observed for a number of months following an acute head injury. Brenner, Friedman, Merritt and Denny-Brown¹¹ found that headache was present at some time after the injury in 69 per cent of the patients, and that it persisted for longer than two months after the injury in 32 per cent. These headaches were characteristically associated with dizziness and nervous symptoms — fears, anxiety, fatigue, irritability and inability to concentrate. The incidence of prolonged headaches was high among patients with nervous or neurotic symptoms prior to injury, those with complicating environmental factors, — including compensation, — those with symptoms of marked immediate emotional reaction to the injury and those with scalp lacerations. It was low among the victims of recreational accidents and in cases in which the head injury was mild. Neither changes in the spinal fluid, the electroencephalogram or the reflexes nor the extent of disorder of consciousness immediately after the injury gave adequate prognosis of subsequent liability to headache. Headache was, however, significantly less frequent in those who had no initial disorder of consciousness.

Friedman and Brenner,¹² in a study of 22 patients with post-traumatic headache, were able to produce headaches identical in character and location by the intravenous injection of histamine. They conclude that it is possible that histamine activates the physiologic mechanism involved in the production of some types of post-traumatic headache.

The symptoms of post-traumatic vertigo and dizziness were subjected to an analysis by Friedman, Brenner and Denny-Brown,¹³ who found them in 51 per cent of 200 patients at some time after the injury and in 34 per cent after discharge from the hospital. True vertigo was present in only 6 per

cent. There was little evidence that post-traumatic dizziness was related to damage to the vestibular end organ. This study showed that both physical and psychologic factors played an important role in the production of prolonged post-traumatic dizziness, since this symptom was characteristically associated with various factors of psychiatric significance such as pretraumatic nervousness and complicating environmental factors during convalescence. It was more frequent in patients with a severe head injury as evidenced by prolonged coma or post-traumatic amnesia.

The factors of importance with regard to disability following head injury in this series were analyzed by Denny-Brown.¹⁴ One hundred and ten (55 per cent) of the patients complained of symptoms after discharge from the hospital. The symptoms were related to a structural physical disorder in 16 patients, to psychiatric symptoms in 70, to headache in 81 and to dizziness in 68. These symptoms were frequently associated, but each occurred alone. The association of headache, dizziness and psychiatric symptoms — the so-called "postconcussion syndrome" — occurred in 30 patients. Factors of unfavorable prognostic significance in relation to return to work within two months and within six months of the injury were analyzed, and in each case features indicative of severity of injury and those indicative of psychologic stress were intermingled. The symptoms associated with prolonged disability, whether the injury had been severe or mild, were predominantly mental symptoms related to anxiety. Denny-Brown concludes that the environmental factors of injury were in total effect more important in accounting for disability than were the factors indicative of severity of injury, but that neither can be neglected in the assessment of prognosis. He adds that the extensive association between head injury and psychiatric factors indicates possibilities for lessening disability by psychiatric treatment.

Adler¹⁵ found mental symptoms in 31.5 per cent of 200 patients with head injuries. Mental symptoms particularly anxiety, were, with headache and dizziness, the most frequent symptoms in convalescence and were the major cause of disability, particularly prolonged disability, following head injury. A number of factors entered into the production of the anxiety symptoms in these patients, the most direct being reproduction of fears related to the injury and elaboration of pre-existing conflicts in relation to social and occupational adjustment.

The relative infrequency of head injury as a cause of serious mental deterioration or a real psychosis is emphasized by the studies of Denny-Brown,¹⁴ Adler¹⁵ and Thompson and McGinnis.¹⁶ The last authors found that only 174 (0.28 per cent) of 61,795 patients admitted to a psychopathic hospital were diagnosed as suffering from post-traumatic

MEDICAL PROGRESS

NEUROLOGY

H HOUSTON MERRITT, M D *

NEW YORK CITY

SOME of the recent significant advances and refinements that concern neurology are discussed in the following sections

ELECTROENCEPHALOGRAPHY

The value of the electroencephalogram in convulsive disorders, head injuries and brain tumors has been well established for some time. In recent years the attention of investigators has turned to a great variety of other conditions, and the literature of the past year contains a large number of reports on the results of the use of the electroencephalogram in cases of alcoholism, delirium, behavior problems in children, psychopathic personality, psychoneurosis, psychosis, migraine and cerebral arteriosclerosis, as well as further studies in cases of epilepsy and brain tumor.

Cobb¹ reports correct localization in 58 per cent of 120 cases of intracranial tumors and abscesses. The tumors that lend themselves most readily to localization are those on the free convexity that are rapidly growing, but even among these there are some that show only a diffuse abnormality. The records in cases with increased intracranial pressure were variable and were more closely related to the degree of consciousness than to the height of the intracranial pressure. The ideal method of localization was the finding of phase-reversal of slow waves, but not infrequently it was necessary to depend on their maximum intensity. It was suggested that the 4-to-7 per second frequency band, or theta rhythm, is associated with lesions in the region of the third ventricle.

Walter and Dovey² in a study of subcortical tumors found that in deep tumors spreading outward the main feature was 6-cycle per second activity from the cortex above the tumor or from the parietotemporal regions or both. A small delta rhythm was sometimes seen immediately above the tumor. In cases with deep tumors not affecting the cortex, the 6-cycle activity was the only significant abnormality. These so-called "theta rhythms" were characteristic of the resting, immature or isolated parietotemporal cortex.

Williams,³ in a study at the Military Hospital for Head Injuries in England, found that larval epileptic outbursts in the electroencephalogram were invariably associated with overt fits, but also that less well defined outbursts were frequently associated with them. These disturbances were found in 25

per cent of 210 cases of post-traumatic epilepsy, as compared with 56 per cent of 275 cases of apparently idiopathic epilepsy. The presence of the typical larval epileptic patterns and other paroxysmal outbursts in the electroencephalogram of patients with head injury usually indicated that clinical seizures would develop later.

Changes in the electroencephalogram in alcoholism are reported by Greenblatt, Levin and di Cori⁴ and by Engel and Rosenbaum.⁵ Greenblatt and his associates found that chronic alcoholism with psychosis was associated with a higher than normal incidence of electroencephalographic abnormalities. Confusion or hallucination was frequently associated with electroencephalographic abnormalities, which tended toward normal with the disappearance of the confusion or hallucination. Engel and Rosenbaum induced acute intoxication in 7 normal subjects with normal electroencephalograms, and noted that this state was accompanied by progressive slowing of the brain waves. The degree of slowing was more significant than the development of any particular wave frequency.

Abnormalities in the electroencephalogram in 49 per cent of 67 children with primary behavior disorders were reported by Gottlieb, Knott and Ashby,⁶ and in 54 per cent of 68 psychopathic personalities by Knott and Gottlieb.⁷ Pacella, Polatin and Nagler⁸ found abnormalities in the electroencephalogram in 64 per cent of 31 patients with obsessive compulsive states.

Irregular slow waves were recorded by Engel, Ferris and Romano,⁹ from the contralateral occipital cortex of 3 patients with scintillating scotoma and homonymous visual-field defect during attacks of migraine. Normal activity was recorded from the ipsilateral occipital cortex and other portions of the brain at the same time.

POST-TRAUMATIC SYNDROME

The frequency of head injuries in the war has led to a number of studies on the post-traumatic syndrome. Ross and McNaughton¹⁰ studied 90 patients, both civilian and military, several months following an injury to the head. A comparison of the 68 patients who had persistent symptoms was made with the 22 who had no complaints. Attention was given to the type of headache, the pre-traumatic personality, the severity of the injury, reports of electroencephalographic and pneumoencephalographic abnormalities, certain ratings of instability and disability as determined by the

*Professor of clinical neurology, College of Physicians and Surgeons, Columbia University; chief of Division of Neuropsychiatry, Montefiore Hospital.

there was some improvement except in 2 per cent of the private patients and 4 per cent of the industrial-compensation cases

Botterell, Keith and Stewart,²⁵ in reporting the management of sciatica due to herniation of the intervertebral disk in Canadian soldiers overseas, stated that they began with a three-week period of conservative treatment, with complete rest in bed. If there was not sufficient improvement to allow patients to re-engage in their regular duties or in those of a less strenuous character, operation was performed, this being done in 51 men. Following operation 29 returned to full duty and 14 to sedentary duty, and 8 were found to be unfit for military duty of any kind.

There was complete relief of pain in 65 per cent of the 400 patients operated on by Poppen.²⁰ There was no improvement in 15 per cent. Sixty per cent of the patients were able to return to their usual activities within six months of the operation, and an additional 35 per cent returned in the next six months. Poppen stresses the fact that the greatest improvement concerned the sciatic pain, relief of which was obtained in 90 per cent of the cases. Low-back discomfort persisted in a large percentage — in 40 per cent when tired and in 60 per cent when attempting to do heavy lifting.

Cervical Disks

Herniation of intervertebral disks in the cervical region is much less frequent than that in the lumbar, and the syndromes produced are less well understood. Michelsen and Mixter²⁶ state that cord compression as a diagnostic criterion of cervical herniation has been overemphasized and that involvement of nerve roots is more frequent. They report 8 cases with a clinical syndrome characterized by root pain and local segmental sensory disturbance, localized muscle atrophy and weakness, absence of cervical lordosis and narrowing of the sixth cervical interspace as seen by x-ray and filling defects following the injection of lipiodol. All the patients had received various types of therapy without benefit. Six were completely relieved of their symptoms by removal of the disk fragments at laminectomy. In 1 case in which this was impossible, the patient was relieved of pain but motor disability persisted. In the remaining patient there was no relief of symptoms following operation.

Twelve cases of rupture of the disk in the cervical region are reported from the Walter Reed Hospital by Spurling and Scoville.²⁷ These authors found that percussion of the spine in the region of the affected disk or tilting of the head and neck to the affected side reproduced the characteristic pain. Complete relief of symptoms resulted from operative removal of the disk fragments in all these cases.

Similar reports on the cervical-disk syndrome are made by Ulmer and Meredith,²⁸ Bucy and

Chenault,²⁹ Elliott and Kremer³⁰ and Browder and Watson.³¹

USE OF PENICILLIN IN INFECTIONS OF THE NERVOUS SYSTEM

During the past year there have been a number of reports on the results of the use of penicillin in infections of the nervous system. Most forms of bacterial meningitis respond to this drug, but the results obtained in meningococcal meningitis have been no better than those achieved with the sulfonamide drugs, and perhaps not so good. Several cases of cavernous sinus thrombosis have been cured. There are also a few preliminary reports on penicillin in the treatment of syphilis of the nervous system.

The amount of the drug that should be used in these various infections and the best route of administration have not as yet been determined. Many authors think that intraspinal administration is necessary because only small amounts of penicillin are present in the cerebrospinal fluid after intramuscular or intravenous injection. The intraspinal injection of penicillin may be followed by symptoms and signs of injury to the roots of the cauda equina and the spinal cord.³² Two deaths as the result of encephalopathy following intracisternal injection of the drug were reported by Neymann, Heilbrunn and Youmans.³³ Application of penicillin to the brain cortex of man or animals may produce convulsive seizures.³⁴ It is my own opinion that the therapeutic value of any drug for infections of the nervous system is not necessarily related to the amount found in the cerebrospinal fluid. It may be necessary to use heroic methods of treatment in potentially fatal diseases, such as pneumococcal meningitis, but in less serious conditions it seems wise at the present state of knowledge to avoid the use of penicillin intraspinaly or intracisternally if other forms of therapy are available.

Meningitis

Rosenberg and Arling³⁵ treated with penicillin 65 patients with meningococcal meningitis at the Great Lakes Naval Hospital, with recovery of 64. The drug was administered intrathecally and intravenously or intramuscularly. In the majority of the patients one or two intrathecal injections of 10,000 units were sufficient, but in several cases four or five injections were needed. No serious untoward effects were noted from the injection of 10,000 units intraspinaly, but the use of larger amounts produced symptoms and signs of meningeal irritation that were severe enough to contraindicate their use. In addition to the intraspinal treatment the patients were given the drug intravenously or intramuscularly, the total dosages by these routes ranging from 20,000 to 900,000 units. The ordinary complications of meningococcal infection — acute monoarthritis, polyarthritis, or

psychoses Abnormalities in neurologic examination were present in 66 per cent The mental impairment presumably due to the head injury was aggravated in some of the patients by complicating factors, such as arteriosclerosis, advancing age, alcoholism and a post-traumatic convulsive state

CAUSALGIA

Injuries to the extremities in the war have awakened an interest in this troublesome problem Recent studies have clearly shown that the symptoms present in patients with causalgia are related to an injury to sympathetic nerve fibers and that this can be relieved by sympathectomy

Speigel and Milowsky¹⁷ found causalgic symptoms in 9 of 275 patients with peripheral nerve injuries examined at the Schick General Hospital in Clinton, Ohio In 8 of these cases the injury was to nerves in the upper extremity, — the brachial plexus in 2, the ulnar in 2, the median in 1, the radial in 2 and the ulnar and median in 1, in 1 case the saphenous nerve was affected Injury to blood vessels was frequently present but was not necessary for the production of the syndrome Complete relief of symptoms was obtained in 7 cases by surgical sympathectomy One patient was relieved by procaine block and 1 by alcohol block of the involved sympathetic nerves The authors emphasize the importance of the early use of diagnostic sympathetic block, followed by surgical sympathectomy Neurolysis, nerve section and periarterial sympathectomy were of no therapeutic value

Mayfield and Devine¹⁸ report 15 cases of causalgia in 737 patients with peripheral nerve injuries who were treated at the Percy Jones General Hospital in Battle Creek, Michigan The nerves involved were the median in 7, the median and ulnar in 1, the brachial plexus in 1 and the sciatic in 6 The lesion of the nerves was incomplete in all cases Certain patients showed vasoconstriction in the causalgic limb, others showed vasodilatation Twelve patients were relieved by preganglionic sympathectomy of the limb, 1 was cured by artificial-fever therapy, and 2 recovered spontaneously The authors state that the personality changes that are always present during the painful stages were due to the patients' reaction to the pain All the patients were classified as normal and with a stable personality when examined by psychiatrists after they had been relieved of the pain

RUPTURED INTERVERTEBRAL DISKS

Lumbar Disks

Mixter and Barr in 1934 elaborated the clinical syndrome of protruded intervertebral disk in the lumbar region Since that time many cases of this

syndrome have been recognized, and in the literature of the past year a number of articles have appeared that summarize the present status of the subject The significant diagnostic features are outlined, and the results obtained with operative and nonoperative treatment are reported

The diagnosis of ruptured disk is discussed by Munro¹⁹ and by Poppen²⁰ They agree that, although this diagnosis can be made in the lumbar region on the basis of a typical history and characteristic physical findings in a large percentage of cases, the use of a contrast media to visualize the subarachnoid space is often necessary, not only for diagnosis but also for accurate localization of the protruded disk or disks An increase in the protein content of the cerebrospinal fluid was found in less than 50 per cent of the cases of both these writers They each conclude that the examination of the cerebrospinal fluid is not of great value in the diagnosis Love,²¹ however, in discussing the differential diagnosis of ruptured disk and spinal-cord tumor states that the finding of a protein content greater than 100 mg per 100 cc is in favor of the diagnosis of tumor

Attention is called by French and Payne²² to the fact that ruptured disks may be large enough to compress the entire cauda equina, and to produce complete or incomplete subarachnoid block They report 8 such cases in which the differential diagnosis from a neoplasm of the cauda equina was almost impossible A similar case was reported by Munro¹⁹

The results of treatment, both surgical and non-surgical, are reported by Grant,²³ Poppen,²⁰ Shinnars and Hamby,²⁴ and Botterell, Keith and Stewart.²⁵ Grant²³ gives the results obtained in 150 patients who were operated on and in 93 treated by conservative measures — rest in bed, leg traction and so forth In 48 per cent of the cases, operation was followed by complete relief of symptoms, in 41 per cent, the patients were improved but still experienced some pain and their work ability was below normal, and in 11 per cent, there was no relief Conservative treatment resulted in complete recovery in 21 (37 per cent) of 57 patients who were bedridden or unable to work, and in partial recovery in 27 (47 per cent) Grant concludes that surgery is not the only possible treatment for ruptured intervertebral disk, since many patients recover with rest, leg traction, back support or other nonoperative means If these measures are not successful, he adds, surgery should be considered

Shinnars and Hamby²⁴ surveyed the results in 87 patients subjected to operation, of whom 63 were private patients and 24 were industrial-compensation cases The results were approximately equal in both groups Relief of symptoms was obtained in 41 per cent of the latter group and in 52 per cent of the former In the remainder of the patients

ing patients, 3 were well, 5 were considerably improved, 5 were moderately improved, and 3 showed no improvement. A thymic tumor was present in only 2 cases. In Viets's series of 15 cases, a thymic tumor was present in 4 patients. The clinical results in 12 patients of this series observed for some months were operative death in 4, complete remission in 2, distinct improvement in 2, moderate improvement in 3 and slight improvement in 1. Favorable results, when they occurred, were not related to the presence of hyperplasia of the thymic gland. The role of this gland in myasthenia gravis is still not settled, and its removal is not recommended by Viets for patients whose symptoms are well controlled by a moderate amount of neostigmine or for those over fifty years of age.

The constancy of ocular signs in myasthenia gravis is stressed by Walsh.⁴⁸ Ptosis, weakness of the orbicularis oculis or limitation of the ocular movements unilaterally or bilaterally was found in all of 63 cases examined at the Johns Hopkins Hospital. They usually appeared early in the course of the disease but were occasionally a late development. Pupillary abnormalities did not occur.

VASCULAR LESIONS OF THE NERVOUS SYSTEM

Attention is called by Scheinker⁴⁹ and Malamud⁵⁰ to the fact that the nervous system may be involved in thromboangitis obliterans and periarteritis nodosa. Scheinker states that the early symptoms may be due to reversible circulatory disturbances (angiospasm and vasoparalysis). If these disturbances are prolonged or of repeated occurrence, irreversible changes are produced in the parenchyma. The histologic criteria for the differential diagnosis of the two conditions are given in detail.

Taylor and Page⁵¹ analyzed the records of 40 patients who died with essential hypertension in an attempt to determine whether any of the clinical features had made it possible to predict that cerebral apoplexy would occur. Among the 19 cases with a fatal cerebral hemorrhage, five symptoms were consistently observed, these were severe occipital and nuchal headache, vertigo or syncope, motor or sensory neurologic disturbances, nosebleeds and retinal hemorrhages in the absence of papilledema or exudate. These findings were negligible or absent among those patients who died of other causes.

Loman and Dameshek⁵² report a case of severe secondary polycythemia with increased intracranial pressure, choked disks and amblyopia in which there was a dissociation between an increased internal pressure in the jugular vein and a normal general venous pressure. The authors conclude that the increased venous pressure in the head and the increased intracranial pressure were due to simple plethora of the intracranial venous system. Venesection resulted

in reduction of both pressures, as well as a subsidence of the choked disks.

Weisman and Adams⁵³ review the neurologic complications of dissecting aortic aneurysm and report the findings in 11 cases from the Boston City Hospital. The clinical syndromes were divided into the following groups: ischemic necrosis of the peripheral nerves, due to extension of the dissection into a major artery of an extremity, with flaccid paralysis and anesthesia of the involved extremity, ischemic necrosis of the spinal cord, resulting from occlusion of the intercostal and lumbar arteries, with flaccid paralysis, anesthesia and sphincter disturbances below the level of the necrosis, and ischemic necrosis of the brain following extension of the dissection of the aneurysm into the carotid or innominate arteries. In some such cases there was confusion, coma, hemiplegia, hemianesthesia or aphasia.

chitis and epididymitis — were not influenced by the treatment, nor was the acute fibrinous pericarditis present in 1 case

Meads, Harris, Samper and Finland³⁶ report 9 cases of meningococcal meningitis treated intraspinously and intramuscularly with penicillin at the Boston City Hospital, with recovery in all cases. In 2 cases, because of poor clinical response and persistence of abnormal bacteriologic and spinal-fluid chemical findings, the penicillin was discontinued and sulfapyrazine was given parenterally and orally. In 1 case, because of persistently positive throat cultures after one week of penicillin therapy, a forty-eight-hour course of sulfadiazine was given orally. The authors conclude that the clinical and laboratory findings in their 9 cases, when viewed in the light of accumulated results of sulfonamide therapy, suggest that in the treatment of Group I meningococcus meningitis the sulfonamides are the drugs of choice. Penicillin may be effective in the doses used, but the response is less favorable than that from sulfonamide therapy.

At the present time the sulfonamides (sulfadiazine) seem to give better results in the treatment of meningococcal meningitis than does penicillin. The 9 per cent mortality rate in 117 penicillin-treated cases reported in the literature is higher than that for any series of cases treated with sulfadiazine. There are, however, reports of cures by penicillin after sulfonamides had failed.

Penicillin has been effective in decreasing the mortality rate in pneumococcal meningitis. In 53 cases reported by various authors³²⁻³⁹ there were 15 deaths, a mortality rate of 28 per cent. Most of the workers agree that the sulfonamides should be used in conjunction with penicillin.

Cavernous Sinus Thrombosis

Cure of single cases of cavernous sinus thrombosis with the administration of penicillin are reported by Nicholson and Anderson,⁴⁰ Goodhill,⁴¹ and Harford, Martin, Hageman and Wood.³⁹ Sulfonamide drugs had been ineffective in all 3 cases.

Syphilis

The value of penicillin in the treatment of syphilis of the nervous system cannot be determined from the reports in the literature. Only a small number of cases have been treated, and none have been followed for a sufficiently long interval to determine the final results. The evaluation of results is further complicated by the fact that many workers do not feel justified in withholding other forms of therapy while giving penicillin. It has been shown, however, by Nelson and Duncan⁴² that in cases of acute syphilitic meningitis the intramuscular injection of penicillin in dosages varying from 600,000 to 4,000,000 units was effective in relieving the symptoms and in producing improvement in the abnormalities in the cerebrospinal fluid.

Stokes and his collaborators⁴³ report beneficial effects on the clinical course and the cerebrospinal-fluid abnormalities in patients with dementia paralytica, tabes dorsalis, optic atrophy and other forms of neurosyphilis. The total number of cases in each of the categories was small, and the period of observation was not sufficient for one to draw any definite conclusions regarding the comparative value of penicillin and previous modes of therapy.

Goldman⁴⁴ treated 18 patients with dementia paralytica with penicillin. Seven were given fever therapy and penicillin intramuscularly. The clinical results obtained did not differ significantly from those previously reported in the literature for fever therapy alone. Eleven patients were treated with intraspinous and intramuscular injections of penicillin alone. Two of these were in poor condition and died within ten days of admission to the hospital. There was some degree of improvement in the remaining 9 patients.

Neymann, Heilbrunn and Youmans⁴⁵ treated 5 cases of dementia paralytica with penicillin by various routes because intravenous and intramuscular injections did not pass the hematoencephalic barrier. They found that the administration of the drug by intracisternal injections in amounts greater than 30,000 units was unsafe because of convulsive seizures and meningeal irritation. Two such patients lapsed into coma and died after the injections. These authors state that the chronic pachymeningitis and leptomeningitis were favorably influenced by the drug, but that the syphilitic involvement of the parenchyma in the depths of the cortex probably remained unchanged.

MYASTHENIA GRAVIS

Neostigmine has been used in the treatment of myasthenia gravis for the last ten years. The results obtained with the use of this drug on 125 patients at the Massachusetts General Hospital since its introduction are presented by Viets.^{46, 46} The theory of the mode of action of the drug is that it allows acetyl choline to remain at the myoneural junction, thus forming the connecting link between the nerve impulse and the muscle. According to Viets, the amount of neostigmine to be administered daily should be sufficient to make the transmission of the impulse efficient. The daily oral dose varies from a few milligrams to an intake as high as 31 mg given in hourly doses, throughout the day and night. The drug can be administered intravenously. Potassium chloride and ephedrine sulfate can be used as adjuvants. Guanidine hydrochloride, although effective in some cases, is not favored by Viets because of the untoward side symptoms, consisting of paresthesias around the mouth and at the fingertips. The role of the thymic gland in the etiology of myasthenia gravis is considered by Blalock⁴⁷ and Viets.⁴⁸ The gland was removed from 20 patients by Blalock. Four patients died. Of the 16 remain-

ing patients, 3 were well, 5 were considerably improved, 5 were moderately improved, and 3 showed no improvement. A thymic tumor was present in only 2 cases. In Viets's series of 15 cases, a thymic tumor was present in 4 patients. The clinical results in 12 patients of this series observed for some months were operative death in 4, complete remission in 2, distinct improvement in 2, moderate improvement in 3 and slight improvement in 1. Favorable results, when they occurred, were not related to the presence of hyperplasia of the thymic gland. The role of this gland in myasthenia gravis is still not settled, and its removal is not recommended by Viets for patients whose symptoms are well controlled by a moderate amount of neostigmine or for those over fifty years of age.

The constancy of ocular signs in myasthenia gravis is stressed by Walsh.⁴⁸ Ptosis, weakness of the orbicularis oculis or limitation of the ocular movements unilaterally or bilaterally was found in all of 63 cases examined at the Johns Hopkins Hospital. They usually appeared early in the course of the disease but were occasionally a late development. Pupillary abnormalities did not occur.

VASCULAR LESIONS OF THE NERVOUS SYSTEM

Attention is called by Scheinker⁴⁹ and Malamud⁵⁰ to the fact that the nervous system may be involved in thromboangitis obliterans and periarteritis nodosa. Scheinker states that the early symptoms may be due to reversible circulatory disturbances (angiospasm and vasoparalysis). If these disturbances are prolonged or of repeated occurrence, irreversible changes are produced in the parenchyma. The histologic criteria for the differential diagnosis of the two conditions are given in detail.

Taylor and Page⁵¹ analyzed the records of 40 patients who died with essential hypertension in an attempt to determine whether any of the clinical features had made it possible to predict that cerebral apoplexy would occur. Among the 19 cases with a fatal cerebral hemorrhage, five symptoms were consistently observed, these were severe occipital and nuchal headache, vertigo or syncope, motor or sensory neurologic disturbances, nosebleeds and retinal hemorrhages in the absence of papilledema or exudate. These findings were negligible or absent among those patients who died of other causes.

Loman and Dameshek⁵² report a case of severe secondary polycythemia with increased intracranial pressure, choked disks and amblyopia in which there was a dissociation between an increased internal pressure in the jugular vein and a normal general venous pressure. The authors conclude that the increased venous pressure in the head and the increased intracranial pressure were due to simple plethora of the intracranial venous system. Venesection resulted

in reduction of both pressures, as well as a subsidence of the choked disks.

Weisman and Adams⁵³ review the neurologic complications of dissecting aortic aneurysm and report the findings in 11 cases from the Boston City Hospital. The clinical syndromes were divided into the following groups: ischemic necrosis of the peripheral nerves, due to extension of the dissection into a major artery of an extremity, with flaccid paralysis and anesthesia of the involved extremity; ischemic necrosis of the spinal cord, resulting from occlusion of the intercostal and lumbar arteries, with flaccid paralysis, anesthesia and sphincter disturbances below the level of the necrosis, and ischemic necrosis of the brain following extension of the dissection of the aneurysm into the carotid or innominate arteries. In some such cases there was confusion, coma, hemiplegia, hemianesthesia or aphasia.

EDITH E. PARRIS, *Assistant Editor*

CASE 31351

PRESENTATION OF CASE

A forty-nine-year-old man was admitted to the hospital complaining of recurrent respiratory infections.

Twelve years before admission he contracted lobar pneumonia, due to a Type 1 pneumococcus. The following year he had another attack, due to a Type 4 pneumococcus. A few months later he again had pneumonia, from which he recovered slowly. One year before admission he suffered two severe attacks of bronchitis, with a cough productive of white or yellow sputum. At times the sputum was malodorous, and on one occasion it contained a small clot of blood. There was no pleurisy or night sweats. Lying on his left side caused severe coughing. Six months before admission, bronchitis recurred and persisted. During this episode he coughed up a great deal of malodorous sputum. The patient became extremely weak and was confined to bed. Two months later, an x-ray film of the chest revealed enlarged hilar nodes, these did not respond to x-ray

therapy. A later film was said to have demonstrated a fluid level. A month before admission he underwent a course of penicillin, following which he became symptom-free.

The past history was noncontributory.

Physical examination revealed a well developed and well nourished man in no acute distress, no outstanding abnormalities were noted.

The temperature was 98°F, the pulse 80, and the respirations 20. The blood pressure was 135 systolic, 95 diastolic.

Examination of the blood showed a white-cell count of 6600, with 66 per cent neutrophils. The hemoglobin was 13.6 gm. The nonprotein nitrogen was 22 mg per 100 cc. A blood Hinton test was negative. The urine was normal.

A chest plate showed a sharply circumscribed mass, approximately 10 cm in diameter, that appeared to rise from the mediastinum (Fig. 1). It moved upward with swallowing, and in its upper portion there was a fluid level. There were no areas of calcification in the mass. There was no interference with aeration of the various lobes. Both halves of the diaphragm were smooth in outline and showed normal motion. The lung fields were clear. There was no evidence of metastases in the visible bones. The mass displaced the esophagus slightly to the left.

On the third hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. HELEN S. PITTMAN. We might start by seeing the x-ray films.

DR. MILFORD D. SCHULZ. Here is a large mass overlying the right border of the heart and the first portion of the aorta. It is smooth in outline and seems to lie in the central portion of the right chest

*On leave of absence.

It contains a fluid level. This, together with the fact that it was reported to move on swallowing, makes one think it had something to do with the respiratory tree. The mass does not seem to have caused a great deal of compression on the lung.

DR. PITTMAN: This seems like a simple, straightforward problem. I have gone over it trying to make it complicated but have not been able to do so. I think that this mediastinal mass was a bronchial cyst, with bronchial communication and recurrent

the organisms that one expects to cause a lung abscess and since this mass does not seem to be out in the lung tissue, the possibility of its representing an old abscess is so remote that I shall pay no attention to it.

A smooth mass in this position is what one finds in a cyst, and I am not going through the differential of all the tumors that could be found here. The history is perfectly characteristic of infection with bronchial plugging, subsequent release of the bron-

FIGURE 1

infection. I shall try to break that down briefly, but I cannot see anything else for it to be.

There was a history going back twelve years. In many cases of chronic bronchopulmonary infection the history of recurrent pneumonia is important. In this patient I do not believe that it is, although he had had three attacks of pneumonia years ago. When talking about bronchial cysts, one has to consider whether they arise in the lung or in the mediastinum, and often one cannot be perfectly sure which is the case.

A cystic mass in the lung may be a burned-out abscess, one with free bronchial communication and which therefore does not produce much surrounding pneumonitis. Since pneumococci are not

chial obstruction and the liberation of large amounts of foul, stinking sputum. There was no calcification in the mass, which argues against a dermoid cyst or tuberculoma, and one is much less likely to find this story of infection and sputum with them.

I think that a diagnosis of bronchial cyst was made and that the patient was sent in for operation. On the outside he was said to have had hilar nodes. I assume that the cyst had been interpreted as a mass of hilar nodes, and since one may not be able to tell by x-ray appearance the difference between a benign and a malignant tumor, it was perfectly proper to give a course of x-ray therapy to see what happened.

My diagnosis is mediastinal cyst arising from the

bronchial or tracheal wall. The fact that it moved with swallowing suggests that it was close to the trachea or to the carina. I believe that there was a bronchial communication and that there has been recurrent infection in the cyst. It was probably on a congenital basis, as most of these are, undoubtedly the operation was complete excision of the cyst.

CLINICAL DIAGNOSIS

Bronchiogenic cyst

DR PITTMAN'S DIAGNOSIS

Mediastinal cyst arising from bronchus

ANATOMICAL DIAGNOSIS

Congenital mediastinal cyst arising from esophagus

PATHOLOGICAL DISCUSSION

DR BENJAMIN CASTLEMAN I am sorry that Dr Richard H Sweet is not here. I shall read portions of his operative note.

The tumor was found to be a cystic one presenting posteriorly to the lung and extending upward behind the right main bronchus a short way and pushing the azygos vein up. It was densely adherent to the lung and also to all the adjacent structures, including the esophagus and the pericardium. The dense adhesions were undoubtedly the result of the infection that he had had early this year.

An incision was made through the overlying pleura, and dissection was first carried posteriorly, freeing the azygos vein and the esophagus from the tumor. The esophagus was quite adherent, but it was relatively easy to dissect it free except at one point where there was a tenting up of the esophagus with what appeared to be a band-like structure going directly into the wall of the cyst, which was extremely thick. This adherent portion was left until a later stage of the operation, and the dissection was then carried around with great difficulty posteriorly and downward on the medial side, freeing the mass from the bronchus. In doing this it was discovered that the cyst had to be freed from the medial surface of the left main bronchus as well as from the carina and the right main bronchus. There was no plane of cleavage and all the dissection had to be done by cutting blindly. The anesthetist had great difficulty because the patient's mouth kept filling up with the foul-smelling contents of the cyst. The amount of the material that accumulated in the throat gradually assumed alarming proportions, and the patient became quite cyanotic. Something drastic had to be done. An incision was therefore made in the wall of the cyst, and the remainder of the contents was removed by aspiration. This immediately stopped the difficulty, and after all the fluid from the throat and trachea had been aspirated there was no further trouble of that nature. The opening of the cyst facilitated its removal, because it was then possible to palpate from within and see where it was necessary to cut in order to separate it from the lung and the remaining portion of the bronchi. The adhesions to the pericardium were very dense, but the cyst was finally removed from the wall of the pericardium without cutting into the latter. It finally became necessary to separate the small bridge of tissue that connected the cyst with the esophagus, and in cutting across this there was a definite channel between the cyst and the esophagus about 4 mm in diameter. This was obviously the point of escape of the cyst contents. There was no communication between the cyst and any portion of the bronchi at tree. The cyst was finally removed without the necessity of doing a lobectomy.

When we received the cyst we observed, of course, all the adhesive bands of connective tissue around

it. The contents had been aspirated, and the inner lining of the cyst had a thick, pebbly, leathery appearance, simulating leukoplakia of the esophagus. The sections showed microscopically that this cyst was lined with a thick layer of stratified squamous epithelium, such as one sees in the esophagus. Beneath the epithelium were glands such as are found in the esophagus, but there was no muscle tissue. In other words, it was made up of a thick layer of connective tissue with an esophageal lining. I felt sure that this was not a true bronchial cyst, because they are lined with respiratory epithelium. I thought of a duplication of the esophagus, such as has been described in children by Ladd and Gross¹ and has been recently explained embryologically by Dr J Lewis Bremer,² but the absence of smooth muscle in the wall of the cyst rules this out. I have asked Dr Bremer of the Department of Anatomy, Harvard Medical School, to come down here today to tell us something about the embryology of this cyst.

DR J LEWIS BREMER I believe that this case just missed being one of tracheoesophageal fistula. If you recall the story of tracheoesophageal fistula, you will remember that the pharynx curves down from the mouth and is provided with four paired lateral pouches or outgrowths. Just below the last pair is another double outgrowth from the ventral surface, this is to become the lungs (Fig 2a)

FIGURE 2

The heart lies at first in the curve of the pharynx, and as it descends the lung bud is drawn down with it. The pharynx between it and the lowest pouches is thereby elongated enormously (Fig 2b). This takes place very early, about the fourth week. The lengthened part of the pharynx becomes flattened laterally, the two lateral walls finally fusing, thus dividing the single pharynx into two tubes, the trachea in front and the esophagus behind. The process begins at the lung bud and proceeds upward (Fig 2c). The trachea does not grow out like the duct of an ordinary gland, but is really part of the esophagus. The only derivatives of the lung bud are the bronchi and lungs.

Normally the separation is complete. Occasionally it is incomplete, with connection between the two tubes at one or more places. Most often the connection is at the lower end near the original lung bud (Fig 2*d*). The esophagus is usually interrupted just above the connection. This is the usual form of tracheoesophageal fistula. Often in these cases there may be at a higher level small tent-shaped pockets from both trachea and esophagus, not meeting each other, but looking as though they had just broken apart. These are traction diverticula. I think that the present case represents a traction diverticulum of the esophagus in the region of and replacing the usual tracheoesophageal fistula (Fig 2*e*). It has swollen up as a large cyst with a narrow stalk and has adhered to the bifurcation of the trachea and to both bronchi (Fig 2*f*).

There was no muscle in the wall of this cyst. The reason for this is that it originated before muscle is present in the esophagus. Muscle develops only where it is needed, as in swallowing, but in a side pocket like this cyst there is no such necessity. Foul-smelling material was brought up with coughing. In coughing the whole chest is compressed, including the mediastinum and, in this case, the cyst, and its contents of foul-smelling retained food escaped through the esophagus.

I have never seen such a case before, but I imagine that this is the explanation of it.

DR. RODOLFO E. HERRERA: Was there any cartilage?

DR. BREMER: There should not be.

DR. LEROY A. SCHALL: No muscularis mucosa.

DR. CASTLEMAN: It consisted of epithelium and connective tissue, in the submucosa there were mucous glands. There was, of course, evidence of long-standing infection.

DR. BREMER: One always finds lymphocytes around the ducts of the tracheal glands.

DR. CASTLEMAN: I suppose this could be called a congenital esophageal cyst for the same reason that a congenital cyst arising from the bronchus is called a bronchiogenic cyst.

The patient did well postoperatively and was discharged in three weeks.

CASE 31352

PRESENTATION OF CASE

A sixty-four-year-old man was admitted to the hospital complaining of back pain.

Seven weeks before admission he suddenly developed severe pain in the lower thoracic spine, which radiated anteriorly to the front of the chest. Analgesics gave no relief. A week later he

went to a community hospital, where the pain was controlled by narcotics. It gradually subsided over a period of several weeks. He rapidly lost strength in his lower extremities, however, and a week after entering the hospital he was unable to walk. On admission to this hospital he was still able to move his legs. During the period of his illness he was compelled for the first time to strain in order to void.

The past history was noncontributory.

The patient was a well developed and well nourished man in no acute distress. The pupils reacted to light and accommodation. The chest was barrel-shaped. The prostate was normal. Pain and touch sensibility was diminished below the seventh thoracic segment, and sensation of position was absent in the feet. The arm, knee, and ankle jerks were present and equal, the abdominal reflexes were absent, and the plantar reflexes doubtful.

The temperature was 99°F, the pulse 90, and the respirations 20. The blood pressure was 100 systolic, 70 diastolic.

On entry, the urine was normal, containing no Bence-Jones protein. Succeeding urine specimens gave + to ++ tests for albumin. The red-cell count was 4,300,000 with a hemoglobin of 80 per cent, and the white-cell count 8000, with 60 per cent neutrophils, 29 per cent lymphocytes, 5 per cent monocytes and 2 per cent eosinophils. Gastric analysis showed 100 units of free hydrochloric acid after 1 mg of histamine. The stools were guaiac negative. A rapid Hinton test was negative. The nonprotein nitrogen was 38 mg per 100 cc, the total protein 7.1 gm, the fasting blood sugar 105 mg, the serum phosphorus 2.8 mg, the alkaline phosphatase 5.2 units, and the acid phosphatase 1.4 units.

X-ray films taken soon after admission showed decalcification of the left pedicle of the sixth thoracic vertebra. The lungs were clear, and the heart was not remarkable. A myelogram was attempted but was unsuccessful. Two weeks later, however, x-ray films showed considerable narrowing of the disk space between the fifth and sixth thoracic vertebrae. The right pedicle of the sixth thoracic vertebra was partially destroyed, and there was a defect of the right lateral portion of the body of this vertebra. Lumbar puncture shortly after admission yielded clear fluid under a pressure equivalent to 90 mm of water. Jugular compression did not cause any rise in pressure, with abdominal compression it rose to 250 mm. No cells were seen. The protein content was 114 mg per 100 cc, and the Wassermann was negative.

A week after admission sensory impairment had become more pronounced but the level remained unchanged. There was complete paralysis of the legs. The knee and ankle jerks were absent. The plantar reflexes were not extensor. The patient had increasing difficulty voiding and was placed on closed bladder drainage. An operation was performed on the sixteenth hospital day.

DIFFERENTIAL DIAGNOSIS

DR ARTHUR L. WATKINS We have a story of only seven weeks' duration, beginning with backache and pain radiating anteriorly, which suggests spinal-root involvement. The simplest explanation might be arthritis, a mechanical back disturbance of some sort, herpes zoster or intercostal neuralgia. But all these are rather easily ruled out by the onset within a week of signs suggesting involvement of the spinal cord, with presumable compression. There was a definite sensory level, and progressive weakness of the legs. Also, lumbar puncture later showed signs of block. So far as localization is concerned, the symptoms suggest a lesion that is compressing the spinal cord at the level of the sixth or seventh thoracic segment, and the x-ray studies give a further lead. We might see the films now.

DR MILFORD D. SCHULZ The pedicles of the sixth segment on the left are decalcified. There is some narrowing of the intervertebral space between the sixth and the fifth segments. Whether that is associated with the lesion or due to something that existed previously, I do not know.

DR WATKINS The report mentioned a later film showing a change in that respect.

DR CHARLES S. KUBIK Also, that the spine showed destruction laterally.

DR SCHULZ I do not see a great deal of change in the second set of films. I wonder whether the appearance of destruction on the lateral surface of this segment may not have been due to rotation rather than actual destruction of bone. No, on looking at it more closely I believe that there is definite destruction: the left side of the sixth body does not seem to be so well formed as the segments above and below.

DR WATKINS There is no widening of the interpedicular space?

DR SCHULZ That is difficult to say without measuring and comparing them to standard curves, but I do not believe there is appreciable widening of the interpediculate spaces.

DR KUBIK Is there any soft-tissue mass?

DR SCHULZ I can see none.

DR WATKINS And no calcification?

DR SCHULZ No. The only definite change is the apparent destruction of the pedicle.

DR WATKINS We have then, with the help of the x-ray films, further confirmation of a lesion that seems to have been at the level of the sixth thoracic vertebra. It might have been due to a ruptured disk, but there does not seem to be much to favor that, although there is some narrowing of the disk space. One would not expect to find decalcification of the vertebra and the pedicle.

So far as infectious processes are concerned, we know that an epidural abscess can give a sudden transverse myelitis, but the course here was rapidly progressive. There were no cells in the spinal fluid, no local tenderness, and no general signs of an in-

fectious process. In tuberculosis of the spine one would not expect to have such a rapid progression of neurologic signs without evidence of more extensive bone destruction, possibly with soft-tissue changes, than is apparent in this case.

I suppose that this could have been a gumma. There is no hint, however, that the patient had ever had syphilis. I presume that the decalcification could have been simply due to pressure from a tumor, with some pulsation from below transmitted to it. I do not know how we can make a diagnosis of gumma. The x-ray studies do not give any lead, and although I cannot rule it out, I shall have to say that there is no evidence for it.

As for vascular lesions, hematomyelia can give neurologic symptoms, but one would expect dissociated sensory loss, without evidence of block or of a destructive lesion in the vertebra. As for other intrinsic cord diseases, multiple sclerosis, central-nervous-system syphilis, syringomyelia and other degenerative lesions can be ruled out because of the block, and the symptoms are in no way suggestive.

So we are left with a diagnosis of tumor. Could it have been an intramedullary tumor? The first symptoms were those of root involvement, and this is much against a primary intramedullary tumor, such as a glioma. The early appearance of bone changes and the rather rapid course are also against that diagnosis. The most frequent tumors involving the spinal cord are the extramedullary intradural tumors, and among these, a meningioma is probably of commonest occurrence. The history is consistent with an extramedullary intradural tumor, since the symptoms began with root pain and the rapid onset of neurologic signs. Perhaps first there may have been some evidence of spasticity, we do not know how lively the reflexes were. There may have been a Babinski sign, and the abdominal reflexes were absent. We do not know how the legs felt: whether they seemed to be hypertonic or whether there was, instead, a rather rapid development of a flaccid type of paralysis, which would be consistent with fairly rapidly progressing compression by a tumor situated in this position. Most of the extramedullary extradural tumors give similar clinical symptoms, and it would be difficult to differentiate them in this case.

It may have been a metastatic lesion, but we do not have any evidence of a primary site. There was free acid in the stomach, and the stool was guaiac negative. So we have nothing suggesting that there was anything wrong in the gastrointestinal tract. The prostate was described as normal. There is a possibility that a renal-cell tumor had metastasized to the spine, — a solitary metastasis, — but we have no evidence of a mass in the kidney region. Some albumin was found in the urine, and there was slight anemia. Against metastatic disease are the normal phosphatase and the fact that the lesion

was small and focal, without evidence of diffuse bone involvement

Among the bone tumors we must consider multiple myeloma — in this case, I suppose, a single myeloma. There was, however, no Bence-Jones protein, and one would not expect to find such a rapid progression of neurologic signs without more evidence of bone involvement. As for hemangioma, these tumors are likelier to cause a more specific x-ray appearance. The rather rapid course, only six weeks, is against a hemangioma. Osteogenic sarcoma would tend to give evidence of extensive bone disease before showing this degree of neurologic involvement.

So this brings us to a primary tumor, either benign or malignant. The most frequent benign lesion is meningioma. Sometimes calcification in the x-ray films gives a lead. A neurofibroma can give a similar appearance. If the tumor was responsible for the narrowing of the disk space, it probably was not a meningioma or neurofibroma. This would suggest a more destructive or invasive tumor, possibly an epidural sarcoma. I do not know, however, whether we can be sure that the narrowing of the disk space was related to the process, it may have been due to an old injury. In this location, narrowing of the intervertebral space is fairly frequent. The report suggests that the narrowing had increased during the hospital stay, but I gather that that is not particularly evident from the x-ray films.

Rare conditions such as dermoid tumors and Hodgkin's disease involving bone seem unlikely. There was no soft-tissue involvement or enlarged lymph nodes in the mediastinum. There was no calcification suggesting dermoid, and the process does not seem to have been as extensive as one would expect in that condition. It could have been a lipoma, but these lesions are likely to be multiple. We do not know how far it extended, but so far as one can tell from the x-ray appearance, it was fairly well localized. I cannot rule out lipoma, but it seems less likely than a meningioma or neurofibroma.

On the law of chances, which one cannot count on too much at these exercises, I am going to conclude that there was a lesion compressing the spinal cord at the level of the sixth thoracic vertebra, presumably a tumor. It was probably extramedullary, and it probably arose in this region, either a meningioma or a neurofibroma, but the rapid course suggests that it may have been a primary epidural sarcoma.

DR JOST MICHELSEN I should like to know more about the urine examinations.

DR KUBIK The sediment contained 5 to 25 white cells and 4 red cells per high-power field, and on one examination there were a few epithelial cells.

DR MICHELSEN There was no urinary infection?

DR KUBIK No cultures were taken.

DR MICHELSEN Does Dr Watkins attach any significance to the albumin?

DR WATKINS It might make one think of hypernephroma. It was the only lead I had.

DR KUBIK The albumin was not present all the time. When the patient was first admitted, there was no albumin, later there was a slight trace.

DR SCHULZ, can you make a diagnosis from the x-ray films?

DR SCHULZ I am sure that I do not know what it is.

DR WILLIAM SWEET I have seen one patient who had a rapidly developing erosion of the pedicle from a rare condition that Dr Watkins did not mention — a neurofibrosarcoma. The tumor arose in the nerve root. When I removed the intraspinal portion of the lesion, I thought that it was a benign tumor. It extended through the intervertebral foramen, and the thoracic surgeon later removed the intrathoracic portion. The intraspinal portion looked benign microscopically, but the intrathoracic portion contained innumerable mitotic figures. The patient subsequently succumbed.

DR KUBIK It was probably a benign tumor that had become malignant.

CLINICAL DIAGNOSIS

Metastatic carcinoma

DR WATKINS'S DIAGNOSES

Spinal-cord compression by tumor at level of sixth thoracic vertebra

Epidural sarcoma?

Meningioma or neurofibroma?

ANATOMICAL DIAGNOSIS

Tuberculosis of vertebra, with extension to dura.

PATHOLOGICAL DISCUSSION

DR KUBIK The Neurosurgical Service suspected that this man had metastatic malignancy, but the possibility of tuberculosis was mentioned once. The X-ray Department favored malignant tumor, either metastatic carcinoma or lymphoma.

When the region was explored, reddish tissue outside the dura, which was thought to be tumor, was found under the sixth dorsal nerve root. The entire lateral wall of the spinal canal was removed, exposing the nerve root in its canal and the tumor over a distance of almost 4 cm. No definite destruction of the vertebral bodies was seen during the removal of pieces of the tumor. The tumor had a dumbbell extension alongside the root through the foramen, and with suction, gelatinous whitish tissue somewhat suggestive of tuberculosis was removed. The dura was not opened.

Microscopical examination showed the mass to be a tuberculous epidural process, presumably extending from tuberculosis of the vertebra, although this was not observed at operation.

DIFFERENTIAL DIAGNOSIS

DR ARTHUR L. WATKINS We have a story of only seven weeks' duration, beginning with backache and pain radiating anteriorly, which suggests spinal-root involvement. The simplest explanation might be arthritis, a mechanical back disturbance of some sort, herpes zoster or intercostal neuralgia. But all these are rather easily ruled out by the onset within a week of signs suggesting involvement of the spinal cord, with presumable compression. There was a definite sensory level, and progressive weakness of the legs. Also, lumbar puncture later showed signs of block. So far as localization is concerned, the symptoms suggest a lesion that is compressing the spinal cord at the level of the sixth or seventh thoracic segment, and the x-ray studies give a further lead. We might see the films now.

DR MILFORD D. SCHULZ The pedicles of the sixth segment on the left are decalcified. There is some narrowing of the intervertebral space between the sixth and the fifth segments. Whether that is associated with the lesion or due to something that existed previously, I do not know.

DR WATKINS The report mentioned a later film showing a change in that respect.

DR CHARLES S. KUBIK Also, that the spine showed destruction laterally.

DR SCHULZ I do not see a great deal of change in the second set of films. I wonder whether the appearance of destruction on the lateral surface of this segment may not have been due to rotation rather than actual destruction of bone. No, on looking at it more closely I believe that there is definite destruction. The left side of the sixth body does not seem to be so well formed as the segments above and below.

DR WATKINS There is no widening of the interpedicular space?

DR SCHULZ That is difficult to say without measuring and comparing them to standard curves, but I do not believe there is appreciable widening of the interpediculate spaces.

DR KUBIK Is there any soft-tissue mass?

DR SCHULZ I can see none.

DR WATKINS And no calcification?

DR SCHULZ No. The only definite change is the apparent destruction of the pedicle.

DR WATKINS We have then, with the help of the x-ray films, further confirmation of a lesion that seems to have been at the level of the sixth thoracic vertebra. It might have been due to a ruptured disk, but there does not seem to be much to favor that, although there is some narrowing of the disk space. One would not expect to find decalcification of the vertebra and the pedicle.

So far as infectious processes are concerned, we know that an epidural abscess can give a sudden transverse myelitis, but the course here was rapidly progressive. There were no cells in the spinal fluid, no local tenderness, and no general signs of an in-

fectious process. In tuberculosis of the spine one would not expect to have such a rapid progression of neurologic signs without evidence of more extensive bone destruction, possibly with soft-tissue changes, than is apparent in this case.

I suppose that this could have been a gumma. There is no hint, however, that the patient had ever had syphilis. I presume that the decalcification could have been simply due to pressure from a tumor, with some pulsation from below transmitted to it. I do not know how we can make a diagnosis of gumma. The x-ray studies do not give any lead, and although I cannot rule it out, I shall have to say that there is no evidence for it.

As for vascular lesions, hematomyelia can give neurologic symptoms, but one would expect dissociated sensory loss, without evidence of block or of a destructive lesion in the vertebra. As for other intrinsic cord diseases, multiple sclerosis, central-nervous-system syphilis, syringomyelia and other degenerative lesions can be ruled out because of the block, and the symptoms are in no way suggestive.

So we are left with a diagnosis of tumor. Could it have been an intramedullary tumor? The first symptoms were those of root involvement, and this is much against a primary intramedullary tumor, such as a glioma. The early appearance of bone changes and the rather rapid course are also against that diagnosis. The most frequent tumors involving the spinal cord are the extramedullary intradural tumors, and among these, a meningioma is probably of commonest occurrence. The history is consistent with an extramedullary intradural tumor, since the symptoms began with root pain and the rapid onset of neurologic signs. Perhaps first there may have been some evidence of spasticity, we do not know how lively the reflexes were. There may have been a Babinski sign, and the abdominal reflexes were absent. We do not know how the legs felt whether they seemed to be hypertonic or whether there was, instead, a rather rapid development of a flaccid type of paralysis, which would be consistent with fairly rapidly progressing compression by a tumor situated in this position. Most of the extramedullary extradural tumors give similar clinical symptoms, and it would be difficult to differentiate them in this case.

It may have been a metastatic lesion, but we do not have any evidence of a primary site. There was free acid in the stomach, and the stool was guaiac negative. So we have nothing suggesting that there was anything wrong in the gastrointestinal tract. The prostate was described as normal. There is a possibility that a renal-cell tumor had metastasized to the spine, — a solitary metastasis, — but we have no evidence of a mass in the kidney region. Some albumin was found in the urine, and there was slight anemia. Against metastatic disease are the normal phosphatase and the fact that the lesion

was small and focal, without evidence of diffuse bone involvement

Among the bone tumors we must consider multiple myeloma—in this case, I suppose, a single myeloma. There was, however, no Bence-Jones protein, and one would not expect to find such a rapid progression of neurologic signs without more evidence of bone involvement. As for hemangioma, these tumors are likelier to cause a more specific x-ray appearance. The rather rapid course, only six weeks, is against a hemangioma. Osteogenic sarcoma would tend to give evidence of extensive bone disease before showing this degree of neurologic involvement.

So this brings us to a primary tumor, either benign or malignant. The most frequent benign lesion is meningioma. Sometimes calcification in the x-ray films gives a lead. A neurofibroma can give a similar appearance. If the tumor was responsible for the narrowing of the disk space, it probably was not a meningioma or neurofibroma. This would suggest a more destructive or invasive tumor, possibly an epidural sarcoma. I do not know, however, whether we can be sure that the narrowing of the disk space was related to the process, it may have been due to an old injury. In this location, narrowing of the intervertebral space is fairly frequent. The report suggests that the narrowing had increased during the hospital stay, but I gather that that is not particularly evident from the x-ray films.

Rare conditions such as dermoid tumors and Hodgkin's disease involving bone seem unlikely. There was no soft-tissue involvement or enlarged lymph nodes in the mediastinum. There was no calcification suggesting dermoid, and the process does not seem to have been as extensive as one would expect in that condition. It could have been a lipoma, but these lesions are likely to be multiple. We do not know how far it extended, but so far as one can tell from the x-ray appearance, it was fairly well localized. I cannot rule out lipoma, but it seems less likely than a meningioma or neurofibroma.

On the law of chances, which one cannot count on too much at these exercises, I am going to conclude that there was a lesion compressing the spinal cord at the level of the sixth thoracic vertebra, presumably a tumor. It was probably extramedullary, and it probably arose in this region, either a meningioma or a neurofibroma, but the rapid course suggests that it may have been a primary epidural sarcoma.

DR. JOST MICHELSEN: I should like to know more about the urine examinations.

DR. KUBIK: The sediment contained 5 to 25 white cells and 4 red cells per high-power field, and on one examination there were a few epithelial cells.

DR. MICHELSEN: There was no urinary infection?

DR. KUBIK: No cultures were taken.

DR. MICHELSEN: Does Dr. Watkins attach any significance to the albumin?

DR. WATKINS: It might make one think of hypernephroma. It was the only lead I had.

DR. KUBIK: The albumin was not present all the time. When the patient was first admitted, there was no albumin, later there was a slight trace.

DR. SCHULZ: Can you make a diagnosis from the x-ray films?

DR. SCHULZ: I am sure that I do not know what it is.

DR. WILLIAM SWEET: I have seen one patient who had a rapidly developing erosion of the pedicle from a rare condition that Dr. Watkins did not mention—a neurofibrosarcoma. The tumor arose in the nerve root. When I removed the intraspinal portion of the lesion, I thought that it was a benign tumor. It extended through the intervertebral foramen, and the thoracic surgeon later removed the intrathoracic portion. The intraspinal portion looked benign microscopically, but the intrathoracic portion contained innumerable mitotic figures. The patient subsequently succumbed.

DR. KUBIK: It was probably a benign tumor that had become malignant.

CLINICAL DIAGNOSIS

Metastatic carcinoma

DR. WATKINS'S DIAGNOSES

Spinal-cord compression by tumor at level of sixth thoracic vertebra

Epidural sarcoma?

Meningioma or neurofibroma?

ANATOMICAL DIAGNOSIS

Tuberculosis of vertebra, with extension to dura

PATHOLOGICAL DISCUSSION

DR. KUBIK: The Neurosurgical Service suspected that this man had metastatic malignancy, but the possibility of tuberculosis was mentioned once. The X-ray Department favored malignant tumor, either metastatic carcinoma or lymphoma.

When the region was explored, reddish tissue outside the dura, which was thought to be tumor, was found under the sixth dorsal nerve root. The entire lateral wall of the spinal canal was removed, exposing the nerve root in its canal and the tumor over a distance of almost 4 cm. No definite destruction of the vertebral bodies was seen during the removal of pieces of the tumor. The tumor had a dumbbell extension alongside the root through the foramen, and with suction, gelatinous whitish tissue somewhat suggestive of tuberculosis was removed. The dura was not opened.

Microscopical examination showed the mass to be a tuberculous epidural process, presumably extending from tuberculosis of the vertebra, although this was not observed at operation.

"IF NOT, WHAT IS IT?"

THE following editorial, which appeared under the above heading in the August 4 issue of *The Christian Science Monitor*, clearly and ably refutes one of the arguments expounded by the sponsors of the Wagner-Murray-Dingell Bill. It is reprinted through the courtesy of the Christian Science Publishing Society

Debate has developed over whether the compulsory sickness insurance called for by the Wagner-Murray-Dingell Bill is socialized medicine. In statements given the press, sponsors of the legislation declared it "is not socialized medicine, it is not state medicine."

The bill provides for social insurance to furnish medical care, and would set up a Government system of medical service. Every eligible person who wished to receive the care offered would be limited in his choice of physician

to doctors who had signed up with the Government. If an insured worker preferred to go to some doctor outside the system, he would have to pay his insurance tax as usual and his doctor besides. Also, it is difficult to see how he could obtain the cash disability payments, making up in part for loss of wages during illness, available to those certified by Government doctors.

The doctors in the system, who according to some estimates would probably number 100,000, would be paid by the Government. They would decide for themselves whether to be paid on a fee, per capita, or salary basis, or a combination. Administration of the system would be directed by the Surgeon General of the United States Public Health Service. The confidential relationship between physician and patient would in a degree be removed by the requirement that the doctor furnish a written report to the Government on each patient and his illness.

Coverage of the plan would extend to a great percentage of the population. Most of the workers would be taxed to pay the costs through weekly pay-roll deductions. Their employers would be similarly taxed. The self-employed would also be brought in. Dependents would be included. Before many years the tax receipts would prove insufficient and, as the bill's sponsors say, the Government would have to help out with a subsidy.

Obviously, when a compulsory system of government-medical-care insurance is set up to embrace the bulk of a people, that is socialized medicine. When the Government hires doctors like postmen and pays them salaries, that is state medicine. The Wagner-Murray-Dingell Bill provides for both.

RESTRICTING THE SALE OF SULFONAMIDES

HARDLY a month has passed in recent years without the appearance in the medical literature of several reports concerning toxic manifestations in persons who took sulfonamide drugs in one form or another. Particularly disturbing are those untoward reactions that occur in persons who have previously been treated with these drugs and are later again exposed to them either through self-medication or on the advice of physicians who are unaware of the previous exposure. Apparently the nature or number of the reactions that have followed self-medication has not sufficiently impressed the proper authorities to induce them to prohibit the uncontrolled sale of sulfonamide preparations. At any rate, in most parts of this country it is still possible to purchase over the counter not only the ordinary sulfonamide tablets but also numerous other preparations, such as nose drops, adhesive-backed bandages, shaving creams and cosmetics, that contain sulfonamide drugs. Any of them may produce serious reactions in sensitized

persons, and by virtue of the fact that many of these preparations are used repeatedly, they may themselves be the cause of sensitization. A review of the dangers from the external use of sulfonamides has recently been published by the Council on Pharmacy and Chemistry of the American Medical Association.¹

Some time ago the Department of Health of the City of New York took cognizance of these dangers and forbade the sale of sulfonamide drugs for internal or external use in the form of powders, ointments or sprays without a prescription. Up to this time, however, no similar restriction has been placed on many other items, such as cosmetics, shaving creams and bandages, containing sulfonamides. The Board of Health has recently enacted an amendment to the Sanitary Code of the City of New York that restricts the dispensing of any and all kinds of preparations containing sulfonamides for internal or external use without a written prescription.² This amendment is in line with recommendations made to that board by the Public Health Relations Committee of the New York Academy of Medicine and with the expressed opinion of many of the nation's leading medical associations.

It would undoubtedly be well for other public-health authorities to follow this example. Such action, however, only emphasizes the duties of the physician in prescribing sulfonamides. He should ascertain beforehand whether the patient has previously been exposed to these drugs and whether a toxic reaction resulted from their use. He should exercise due caution in their use when he does prescribe them. Likewise, patients who have had such a reaction should be made aware of the dangers of its repetition and of the need for close medical supervision when it is necessary to give one of these drugs again. It must also be borne in mind that evidence of sensitization to a sulfonamide may not necessarily manifest itself during the first course of treatment and yet may appear in a rather violent form as soon as the drug is taken a second time. For that reason every patient should be made aware of the fact that he is taking or has taken a sulfonamide, even if no untoward effects followed its use.

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

POLIOMYELITIS AND BATHING BEACHES

Simultaneously with the report of an increase in the reported cases of poliomyelitis there arises renewed public interest in the relation of bathing beaches to the spread of the disease. When a child who has been swimming becomes infected, panic among bathers often develops and a popular demand to close the beach results.

Epidemiologists generally agree that poliomyelitis is an upper respiratory, rather than a water-borne, disease and that human contacts are responsible for its spread. For that reason the attention of the public should be directed primarily toward the avoidance of crowds in theaters, stores and other gathering places.

The department has consistently opposed the closing of approved bathing sites in Massachusetts during the period of high prevalence of poliomyelitis unless unusual circumstances exist. Moreover, the approved beaches in the Commonwealth are not located where they can be polluted by sewage. Sanitary surveys are made periodically, and the water is analyzed bacterially and chemically.

The closing of approved beaches in this state should be considered only when theaters, schools and churches are closed and all public meetings cancelled. Action of this kind is taken more frequently because the public demands it than because such closing prevents the spread of the disease.

BOOK REVIEWS

The Art of Resuscitation. By Paluel J. Flagg, M.D. 8°, cloth, 453 pp., with 176 illustrations. New York: Reinhold Publishing Corporation, 1944. \$5.00.

This book is essentially a combination of the twenty-five years of clinical and practical experiences of the author, a review of recent military literature on asphyxia and the investigations of the Society for the Prevention of Asphyxial Death. The basis of thought is, "What is to be treated is more important than how treatment is to be applied." The frontispiece is an interesting schematic representation of the entire text.

The book is divided into seven parts. Part I deals with the definition of asphyxia, contrasting the British concept of cessation of pulse with the American concept of cessation of respiration. A brief historical background, as well as some detailed publicity for the Society for the Prevention of Asphyxial Death, is included. Part II, entitled "Asphyxia as a Generic Problem," is a sketchy review of experimental physiology and an accepted listing of the causes of asphyxia. Part III, entitled "The Principles of Resuscitation," is a discussion of the four accepted types of anoxia— anoxic, anemic, stagnant and histotoxic — and of the causes and indications for treatment. The stages of asphyxia, with their signs and symptoms, are listed. A detailed description of methods of resuscitation and an illustrative review of resuscitative apparatus are also presented. Included in this section are the modern concepts and equipment for handling and transporting unconscious patients. Part IV contains essentially the meat of the whole book. It is a detailed description and discussion of the treatment of specific types of asphyxia, listed as follows: neonatorum, high altitude, carbon monoxide poisoning, submersion, anesthesia, poliomyelitis, electrocution, fire-fighting gases, mechanical obstruction, pathologic respiratory obstruction and clinical diseases. Part V, entitled "The Field of Asphyxia and Resuscitation," covers the organization and importance, from a sociologic and economic standpoint, of the various groups, including medicine, dentistry, public health, child welfare, Army, Navy and civilian defense. In Part VI the author expounds his ideas and visions for a rebirth of the science of pneumatology. This science is built on three equally important subjects — anesthesia, resuscitation and gas therapy. Of this equilateral triangle, two books already have been published by the author — *Art of Anesthesia* and the present book.

Like *Art of Anesthesia*, this book is well written and easy to read. At times the author's interests and opinions are overly stressed and elaborated. The book contains many interesting detailed and instructive illustrations. It is an excellent reference book for information and data on resuscitation not only for physicians and dentists but also for their trained technicians.

The Etiology, Diagnosis and Treatment of Amebiasis. By Charles F. Craig, M.D. 8°, cloth, 332 pp., with 45 illustrations and 10 tables. Baltimore: Williams and Wilkins Company, 1944. \$4.50.

Dr. Craig's new book on amebiasis maintains the same high standard of excellence that he achieved in his earlier work on the same subject, entitled *Amebiasis and Amebic Dysentery*.

The two books have nearly the same number of pages, but the space devoted to the pathology of amebiasis has been considerably expanded in the new volume, and that given to some of the other subjects has been correspondingly curtailed. Because diagnosis in obscure cases depends greatly on a clear understanding of the pathologic lesions produced by amebic infection, the more complete account of the pathology is especially valuable.

The subject matter is notable for the opinions of the author, which are based on his own long experience with amebiasis. The illustrations are excellent.

The book can be highly recommended to students and to practitioners of medicine.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

The Reticulo-Endothelial System in Sulfonamide Activity. By Frank T. Maher, M.D., assistant professor of pharmacognosy and pharmacology, University of Illinois. Illinois Monographs in the Medical Sciences, Vol. V, Nos. 1-2. 4°, paper, 232 pp., with 23 illustrations. Urbana: University of Illinois Press, 1944. \$2.50 (paper bound) and \$3.00 (cloth bound).

The purpose of this monograph is to evaluate reticulo-endothelial activity in sulfonamide chemotherapy in experimental animals, and the author believes that the results presented strongly indicate its vital importance. It is his intention to continue his studies in this special field, with the hope that light will be thrown on the means by which the sulfonamide drugs accomplish their therapeutic effects. The monograph was presented in 1941 as a dissertation for the degree of philosophy in pharmacology at the Graduate School of the University of Illinois. The text is well documented, and a list of over six hundred pertinent references is appended. The book is well printed, with a good type on good paper.

A Test for Color Blindness. By P. B. Wiltberger, M.D. 12°, paper, 7 pp., illustrated. Columbus, Ohio: College Book Company, 1944. \$1.00.

This simple test claims readily to separate color blind persons from normal and color-weak persons. This new test was first published by the author in 1941. He claims that it is accurate and physiologic and cannot be memorized and that the person being tested need not be asked what color he sees and need not know the name of a single color.

NOTICES

ANNOUNCEMENT

Dr. Nathaniel M. Stone announces the removal of his office from 475 to 371 Commonwealth Avenue, Boston.

PHILLIPS SOCIETY

Dr. Eugene Kellersberger, government consultant on tropical diseases and former medical missionary to Africa, will give an illustrated lecture "Leprosy and Trypanosomiasis" at the Beth Israel Hospital amphitheater, Thursday, September 6, at 8:00 p.m. This is sponsored by the Phillips Society of Tufts College Medical School.

NEW ENGLAND HOSPITAL FOR WOMEN AND CHILDREN

The monthly clinical conference and meeting of the staff of the New England Hospital for Women and Children will be held on Thursday, September 6, in the classroom of the Nurses' Residence at 7:15 p.m. There will be a discussion of penicillin therapy with presentation of cases. Dr. Ann P. D. Manton will be chairman.

COARCTATION OF THE AORTA*

Experimental Studies regarding Its Surgical Correction

ROBERT E. GROSS, M.D.,† AND CHARLES A. HUFNAGEL, M.D.‡

BOSTON

COARCTATION of the aorta is an unusual abnormality, but is found with sufficient frequency and is accompanied by severe enough complications to warrant a search for technical methods leading to its surgical correction in selected cases. Many persons with this disease have a reasonably long life and suffer relatively little incapacitation. A high degree of obstruction — or a complete block — in this arterial pathway carries a distinct hazard, however, because of the possibility of certain complications. In the first place, aneurysmal dilatation of the aorta may arise above or below the constricted zone. Secondly, a dissecting aneurysm may originate in the anomalous and sclerotic aortic wall. Thirdly, rupture of the aorta has occasionally been observed. Fourthly, *Streptococcus viridans* infection may become superimposed on the lesion. Last and most important of all, severe hypertension may develop in the upper part of the body. Following this, there may be cardiac failure, cerebral hemorrhage or other ill effects of the hypertensive state. Coarctation of the aorta usually causes few symptoms in childhood years. If important sequelae appear, they are likeliest to manifest themselves in midlife. Although some of these aortic obstructions are well tolerated for long periods, there seems to be little question that in any large series of patients the average span of life is greatly diminished below the normal expectancy.

Little attention has been given to the possibility of surgical alleviation of this congenital malformation. Perhaps experimenters have been disheartened by the great size of the blood vessels concerned and also by the inaccessibility of the structures within the mediastinum. The opening of a new chapter in therapeutic endeavors by the surgical closure of a patent ductus arteriosus has naturally led us to the belief that nearby abnormalities in

the aorta may be subject to some form of correction.

In March, 1938, at the time of beginning the present laboratory investigations, we were not aware of any other attempts to develop methods for the treatment of coarctation of the aorta. Within recent months there has come to publication the work of Blalock and Park,¹ as well as that of Blakemore and Lord,² relative to surgical approaches to this problem. We should like to place on record the following observations that have been made in the laboratory during the last seven years. These experiments have been less extensive than was originally planned, and have been curtailed by the exigencies of war. Nevertheless, they have progressed to a point where we believe that a method has been devised that is feasible for the treatment of coarctation of the aorta in human subjects.

THEORETICAL CONSIDERATIONS

Surgical attack for coarctation of the aorta could conceivably take four different forms. In the first place, the constricted zone might be by-passed by the establishment of a collateral channel. This general principle has been expounded by Blalock and Park,¹ who divided the upper thoracic aorta of dogs and closed the two ends separately. The left subclavian artery was then severed at the base of the neck, and its proximal end was turned downward so that it could be sewed into the aorta below the artificially produced obstruction. This provided a by-pass that permitted blood to flow directly from the upper aortic segment into the lower one. This method, however, has definite limitations because the shunt probably cannot transmit as much blood as the thoracic aorta normally carries. On the other hand, it is quite possible that in human subjects such a by-pass would be all that is required for alleviation of any hypertension. Probably the greatest drawback to the procedure would be its obvious destruction of existing

†Assistant professor of surgery, Harvard Medical School.

‡Arthur Tracy Cabot Fellow, Harvard Medical School.

collateral pathways that are known to come from branches of this subclavian artery in human beings with coarctation of the aorta

In the second place, the constricted portion of the aorta might be excised and the resulting gap bridged by the implantation of a segment of vein, utilizing the technic of Blakemore and Lord.² These authors have shown that in the dog it is feasible to replace a segment of aorta in this way. In human beings, however, it would be exceedingly difficult to obtain a segment of vein large enough for the graft. It is possible that a portion of the inferior vena cava of the same patient might be employed, or indeed a segment could be secured from autopsy material of another subject. A second drawback to the nonsuture method would be the narrowness of the aortic lumen that is necessarily imposed by the use of *vitalium* cuffs. This would be a particularly deterrent factor in young persons because the lumen of the vessel (at the metal cuffs) would be kept from increasing in diameter as the patient grew into adult life.

In the third place it is conceivable that a constricted portion of the aorta could be excised and the resulting gap bridged by implanting into it, with end-to-end suture, a segment of a vessel that had been preserved from autopsy on another subject. The practicality of such a transplant to the aorta was shown by Carrel.³ Additional promising results along this line have likewise been obtained by us in dogs, these we hope to report at a future date.

Lastly, a direct attack could be made on the lesion by cutting out the constricted segment, freeing the aortic arch and thoracic aorta and bringing the remaining ends together by primary end-to-end suture. Toward this type of therapy most of our experimental work has been directed.

LABORATORY PROCEDURE AND OPERATIVE RESULTS

Mongrel dogs with a wide range of weight, all above 18 kilograms, were employed. Operations were undertaken with intravenous Nembutal or with inhalation ether anesthesia. A tube was always placed in the trachea for administration of air under positive pressure while the left pleural cavity was open. In the earlier experiments a generous anterolateral incision in the third interspace was used, but in all subsequent operations a posterior approach (Fig 1) was found to be much more advantageous. The scapula was drawn forward, and the thorax was entered in the fourth or fifth interspace. Above this intercostal incision, one rib neck was sectioned, and below it two ribs were cut to allow sufficient exposure through the bony cage. The left lung was allowed to collapse partially while the chest was open. The distal part of the aortic arch and the superior part of the thoracic aorta were freed from the underlying vertebral column. The dissection of the aorta from its bed carried considerable risk of hemorrhage if the inter-

costal vessels were inadvertently torn off at their origins from the aorta, if this occurred, blood dissected along in the subadventitial spaces of the aorta, and such bleeding was extremely difficult to control. Conversely, if the aorta was carefully and gradually raised so that each intercostal artery could be doubly ligated and divided, the mobilization of the aorta could be completed with safety and little delay. The thoracic duct was identified and was always assiduously avoided.

The field was then ready for practice in the steps of division and reconstruction of the aorta. Two

FIGURE 1 General Exposure Obtained through a Posterior Thoracic Incision

Special clamps are applied to aorta, which is then divided

clamps, several centimeters apart, were placed across the vessel to obstruct it completely, between them the aorta could be divided (Fig 1). In some cases (Table 1), a segment of aorta was cut out and discarded; there was always enough elasticity in the remaining aortic limbs to permit the cut ends to be drawn together.

The aortic clamps received a great deal of consideration and experimentation. Kelly clamps, Kocher clamps, enterostomy clamps and Bethune tourniquets were tried and discarded for one reason or another. Finally, two homemade instruments were devised from straight gastroenterostomy clamps (Fig 2), and these gave great satisfaction. The blades were sawed off and the ends fitted with a small interlocking peg, so that the blades would

not wiggle sideways when closed. The longitudinal slit in the jaws ensured against any sideslipping of the clamp on the grasped aorta. Cross markings were filed in the jaws to preclude end slipping. The

have not shown any important damage to the aortic intima or outer wall at the sites where these clamps had been used.

The total obstruction of the aorta had no im-

*On autopsy no adequate cause for death could be found in these animals. It is possible that intracranial disturbances during the period of aortic occlusion contributed to these fatalities.

the sectioned aorta. Furthermore, they provided good handles for the assistant to steady the ends of the aorta and to pull them together so that there would be no tension on the suture line while the stitches were being placed. Post-mortem studies

minimal degree, usually slowing. In no case did a complete obstruction of the aorta prove fatal, and indeed it never produced cardiac changes of more than momentary interest.

Division of the aorta was followed by direct

end-to-end suture of the vessel, using thoroughly oiled No 00000 Deknatel silk carried on an atraumatic straight needle, 15 mm long. With great

tension on the suture line. Three general types of suturing were employed.

In a few cases the ends of the aorta were directly

FIGURE 3 Details of the End-to-End Suture of the Divided Aorta

1 The aorta is temporarily rotated so that the back wall can be stitched first. 2 The back wall is sutured with a continuous, evert ing stitch that includes the full thickness of the aortic wall. 3 The aorta is allowed to rotate back into normal position, the back wall suture being complete, the stitch is carried around onto the front wall. 4 The anastomosis is complete, the edges of the aorta being everted. 5 A cross section shows that the intimas of the upper and lower segments are in contact with each other.

care, the first assistant held the two aortic clamps in such a way that they were pushed toward each other, hence the ends of the aorta came together and could be sewed while there was absolutely no

abutted to one another so that intima lay to intima media to media and adventitia to adventitia. To obtain this anatomic reconstruction, a continuous over-and-over suture was used to pierce the ad-

ventitia and media, but it did not include the intima, since we believed that it would be deleterious to have the silk presenting within the lumen of the aorta. In some animals this gave a satisfactory type of repair, but in others there was too much bleeding from the suture line after the clamps were removed. In spite of the theoretical and ideal considerations of attempting to keep all silk out of the aortic lumen, it was concluded that this type of repair was unreliable, and it was accordingly abandoned.

In several animals, a second form of repair was employed. The aortic ends were accurately approximated, — intima to intima, media to media and adventitia to adventitia, — with a continuous over-and-over silk stitch that included all the layers of the aortic wall. Although a firm and generous bite of the media was taken, only a millimeter or so of the intima was included in each stitch so that the amount of silk showing inside of the lumen was reduced to a bare minimum. This form of repair was distinctly superior to that described in the last paragraph, but it was by no means perfect in all cases. It, too, was occasionally followed by oozing or free bleeding from the suture line after the clamps were removed. To arrest such hemorrhage was usually time-consuming and difficult. In 3 dogs there was secondary hemorrhage at the suture line one to three days after operation, in 1 of these the loss of blood was copious enough to cause death. Surprisingly enough, the exposure of small bits of the silk stitches in the aortic lumen did not seem to present a serious drawback so far as induction of local clotting was concerned. Yet the method was discarded because it could not be counted on to give adequate hemostasis in all cases.

In the most recent animals, a third type of suture has been used, which appears to give a thoroughly reliable reconstruction. This is best described as a continuous mattress stitch, placed in such a way that the entire thickness of each aortic end is everted (Fig. 3). When each stitch is made sufficiently taut, intima is brought to intima and there is little if any silk showing on the internal surface of the anastomosis. After each stitch is taken, the silk thread is drawn up snugly and is held by a second assistant, whose sole duty is to keep it at just the right tension and to prevent the previously placed stitches from loosening. The anastomosis is begun on the posterior wall, where it is most difficult, and is carried around to and completed on the anterior surface. From time to time a little saline solution is dripped on the aorta to keep its inner and outer surfaces moist. After the continuous stitching is completed, the remaining piece of silk is tied to the original end of the silk. The aortic clamps are then removed, the lower one first. It is seldom that more than a few drops of blood exude from the suture line. If the stitching has been accurately done, there is no bleeding whatever from the anas-

tomosis line when the clamps are taken off. With increasing experience, it was found that such an anastomosis could be completed in fifteen to twenty minutes. This type of end-to-end reconstruction proved to be eminently satisfactory. It produced no constriction of the aortic tube at the site of anastomosis, indeed, the eversion of the ends tended to make the internal diameter of the aorta a little

FIGURE 4. *Operative Results*

The upper photograph shows Dog 14 three months after excision of 1.5 cm. of the thoracic aorta and suture of the aorta. There is no paralysis of the hind legs. The lower one shows Dog 10 one year after excision of 2 cm. of the thoracic aorta and suture of the aorta. There is no hindquarter paralysis.

greater at this point than above and below the anastomosis (Fig. 5).

In the early part of the suture work, bleeding often occurred at the suture line after the aortic clamps were removed. In minor degrees this was not difficult to stop, but with larger leaks the area was buttressed for some minutes with a piece of skeletal muscle, fibrin foam or gauze pack. As we drew toward the completion of our operative series, we became thoroughly convinced that all these measures were poor makeshifts and were completely unnecessary if an accurate and careful repair of the third type was made.

Whenever clamps were removed from an obstructed aorta, the heart rate increased greatly and the work of the organ was obviously enormously augmented. The period of subsequent slowing of the heart usually required several minutes. This temporary rise in the pulse rate did not often seem

to be a serious affair, but 1 dog (Dog 3) died at this time — apparently of cardiac strain. It became evident, however, that the momentary embarrassment occasioned by removal of the clamps could be

FIGURE 5 Roentgenogram of a Barium-Injected Specimen of Aorta (Dog 14)

This was taken three months after division and end-to-end re-suture, with anastomosis at the level of the arrows. There is no constriction at this site.

greatly reduced if the clamps were taken off slowly in order to allow a gradual readjustment in the vascular system.

Although it had been anticipated that intraluminal clotting at the site of anastomosis might be a serious and deterrent factor to such operative procedures, this did not prove to be so. In no case was heparin or dicumarol used during or after the operation. In several animals there were clots 1 or 2 mm in size on the inner surface of the suture line, but these seemed to be of no consequence. There was a marked tendency for endothelium to cover them over in a short time. In 3 other dogs (Dogs 6, 8 and 9), all of which had either the first or the second type of anastomosis, there was a considerable degree of luminal blockage by clot at the operative site. All these dogs died within twenty-four hours after operation, and it is conceivable that clotting was promoted by the reduced blood flow, which was present in an animal dying of other causes. Except for these 3 dogs, all the animals had a satisfactory lumen of the aorta, as judged by the presence of a good pulsation in the femoral arteries and by inspection of the aortic specimen at autopsy.

A serious complication of these aortic operations appeared in the form of hindquarter paralysis in Dogs 12 and 13. Spinal-cord examinations showed diffuse degenerative changes, which had presumably

resulted from local ischemia. We were reasonably certain that such ischemia was not due to post-operative thrombosis at the site of aortic anastomosis, because these dogs had good femoral pulsations during life and had adequate lumens of the aortas when examined at autopsy. We therefore concluded that the spinal-cord damage had occurred while the aorta was obstructed by clamps during operation.

To study further the effects of temporary obstruction of the aorta, especially in relation to development of hind-limb paralysis, 20 additional dogs were operated on by opening the chest, placing a clamp on the upper thoracic aorta for a given number of minutes and then releasing the aorta. The chests were closed, and the dogs were observed for periods varying from a week to two months. Table 2 lists all these observations; it furthermore includes all the dogs from Table 1. The table is arranged in such a way as to emphasize the time during which the aorta was kept completely obstructed; these periods varied from four and a half to sixty minutes. Some dogs with occlusion of the aorta for forty-five to fifty minutes developed no paralysis, whereas others with shorter periods of aortic obstruction showed neurologic changes. In no case did paralysis develop when the aorta was obstructed for less than ten minutes. Of considerable interest are Dogs 19, 20, 21, 13, 15, 14 and 29, during operation the entire back of each animal was packed in ice. Only 1 of these developed paralysis. It seemed to us that the cooling of the animal, and probably reduction of its oxygen needs, had a distinct effect

FIGURE 6 Specimen from Dog 14

This was removed three months after end-to-end suture of the aorta. The arrows indicate the operative site. Healing of the aorta is excellent.

in sparing the spinal cord from damage during the temporary period of reduced blood flow.

Colson,⁴ Carrel⁵ and Blalock and Park¹ have commented on the correlation of aortic obstruction and hind-limb paralysis, and such studies have

been furthered by the experiments here recorded It is quite important, however, to point out that when aortic operations are performed in human subjects, there is little likelihood of neurologic complications from temporary aortic obstruction if there is an adequate collateral circulation, such as is uniformly found with coarctation of the aorta This belief is substantiated by the observations of Alexander and Byron,⁶ who, without deleterious neurologic effects, resected an aneurysm of the thoracic aorta in the presence of a coarctation of this vessel

SUMMARY AND CONCLUSIONS

An attempt has been made to find a surgical procedure that is adaptable for the correction of coarctation of the aorta in human subjects Theoretically, it would be possible to excise such a constricted portion of the vessel and to reunite its upper and lower segments This principle has been tested in the laboratory by completely dividing the upper thoracic aorta, or excising a segment of it, and reconstructing the vessel by end-to-end suture The outcome of these experiments leads us to believe that it is technically feasible to remove a narrowed portion of the aorta in man and to re-establish its continuity by careful and accurate end-to-end anastomosis by the method herein described

clamps, the constricted segment was excised and the remaining ends of the aorta were sewed together Through all this the child was in a satisfactory condition As soon, however, as the clamps were removed from the aorta and the enormous vascular bed was opened up, the heart suddenly went into uncontrollable dilatation and the child died This catastrophe again emphasizes the point that the aortic clamps must be removed slowly The second patient was a twelve-year-old girl for whom surgical therapy was undertaken because of marked hypertension The systolic pressure was frequently recorded at 215 and at no examination was it below 190 No pulsations could be felt in the groins or legs, and no blood-pressure readings could be obtained in the legs Operation was performed on July 6 1945 The aorta appeared to be completely blocked about 1 cm beyond the origin of the left subclavian artery The aorta was doubly clamped, and the constricted area was excised (Examination of the interior of this specimen showed no opening between its two ends) The aorta was repaired by direct end-to-end anastomosis The clamps were gradually released, a full ten minutes being taken before opening them fully There were no deleterious effects on the heart The procedure was tolerated exceedingly well, the wound healed per primam The patient was discharged from the hospital in a satisfactory condition on the nineteenth postoperative day The systolic pressure in the arms had dropped to 140 Femoral pulsations could be readily felt, and the systolic pressure in the legs was 145

THE NEED OF FACILITIES FOR THE CARE OF FEEBLE-MINDED INFANTS AND YOUNG CHILDREN

ISOBEL V DUGUID*

BOSTON

THE protective care of mentally defective infants and young children in Massachusetts is an acutely serious problem for their parents. Some are advised, or decide independently, not to take home from the hospital the infant recognized at birth to be grossly defective. Others are slower to realize the meaning of retarded development, and only when faced with increasing difficulties in the care and management of the defective child in the household group with normal children do they come to the decision that separation is desirable. Such a decision is sometimes deferred until the behavior problem and the effect on the other children, as well as on the parents, have become a hazard to the well-being of the family group. Physicians and parents frequently turn to the medical social worker for advice, in the hope that she can suggest and arrange suitable placement.

It has been known that state custodial care of these children has been insufficient to provide for more than a small number of those needing such care. There are approximately 4000 feeble-minded persons of all ages on the waiting lists of state schools for the feeble-minded. The State Infirmary at Tewksbury, an institution under the Department of Public Welfare, has accepted temporary care of some of these infants, although they are suitable charges of the Department of Mental Health. About 50 such infants are now cared for at the infirmary, and there is a waiting list for admission. Private resources within the Commonwealth are negligible (30 beds). In a study made in 1941, only 51 children under five years of age were found to be in the care of state institutions for the feeble-minded†. It seems obvious that rarely can prompt institutional admission be assured, even in the most urgent cases. Hence, it is not surprising that the social worker consulted after the knowledge of the problem has come to the parents, and often after the doctor has unequivocally advised institutional care, or consulted later in the childhood of the defective, when the burden of care has attained unbearable proportions, finds herself unable to offer a satisfactory solution in placement outside the home.

* * *

Recently, the members of a committee‡ sponsored by the New England District of the American

Association of Medical Social Workers have brought together evidence from their experience in the care of these infants and young children as the parents have sought their help. To focus the problem, it was decided to account for all mentally defective children under six years of age known to these workers between January 1, 1943, and June 30, 1944. There were 189 such children, of whom 61 were under one year, and 99 under two years of age. There were 113 boys and 76 girls.

The reports from medical social workers who were asked to help in caring for these children were supplied by the following agencies and hospitals (in Boston unless otherwise stated)

State departments	56
Public Welfare	40
Public Health	10
Education (Division of the Blind)	6
Social service departments of hospitals	133
Children's Hospital	75
Massachusetts General Hospital	23
Boston Dispensary	7
Massachusetts Eye and Ear Infirmary	6
Boston City Hospital	4
Cambridge Hospital, Cambridge	3
Salem Hospital, Salem	3
St. Luke's Hospital, New Bedford	3
New England Hospital for Women and Children	2
Springfield Hospital, Springfield	2
Quincy Hospital, Quincy	2
Beth Israel Hospital	1
Boston Lying-in Hospital	1
Memorial Hospital, Worcester	1

189

The fact that the parents of these 189 children were referred to social-service departments for advice is evidence that in each case problems were presented that the parents were unable to meet without counsel or assistance. Actually in a large majority of the cases the complications were extremely serious. All the children were feeble-minded. Nine were classified as idiots and 26 as mongols, 27 were hydrocephalic and 3 microcephalic, and many had additional neurologic or physical defects. In 60 cases the defective was the only child, in 99 cases there were one to three other children, in 26 cases there were more than three other children, and in 4 cases information regarding the number of children was lacking. Social situations within the families supplied further complications. In at least 28 cases the fathers were known to be in the armed services, in 17 the parents were divorced, in 12 the children were illegitimate, in 5 the father was dead, in 2 the mother was dead, in 2 the father was in prison, in 1 the mother was in a reformatory,

†Feeble-Minded Children as Massachusetts Problem. 63 pp. Boston Massachusetts Child Council, 1941.

‡The members of this committee are as follows: Isobel V. Duguid, chairman, Massachusetts General Hospital; Flora Burton, Massachusetts

and in 1 she was in a state school for the feeble-minded

In 80 cases placement was arranged, but of the 54 children placed in state institutions 39 were at the Tewksbury State Hospital and Infirmary, which is primarily responsible for the care of the chronic indigent sick, not the feeble-minded. Only 4 were admitted to state schools for the feeble-minded — 3 at the Wrentham school and 1 at Belchertown. Many of the other placements were either temporary or unsatisfactory, and replacement was advised in 15 cases.

As of June 30, 1944, the terminal date of the study, only 28 children had placement that could be considered permanent. Thirty-three children had died. Of the 128 others, institutional care had been recommended for all but 21, and in 54 cases it was considered to be urgent, in at least 75 cases of this group application had been made at one or more state institutions.

Among the children for whom institutional care could not be secured, characteristic problems were the following:

An only child, aged five at the close of the study, is boarded in a foster home by the mother, a widow, at \$20 a week. The mother has been the sole support of the child since the father's death three years previously. She is a cashier in a restaurant, earning \$25 a week, and works overtime to increase her income. The child is on a waiting list for a state school for the feeble-minded.

A boy, aged 4, at home at the close of the study, is one of seven children under fifteen years of age, one of whom, aged nine, is also feeble-minded. The four-year-old child, an idiot, is utterly helpless. Both children are a great strain on the mother and should be separated from the normal children.

A two-year-old girl, the eleventh child in the family, is a mongolian idiot. Her care involves neglect of the other children.

A four-year-old boy of extremely low-grade mentality is a serious behavior problem, since he is irresponsible and abusive of two younger normal children and needing constant watching by the mother.

A three-year-old feeble-minded boy, whose father is serving in the Marine Corps, is the middle one of three children. He is a serious burden to his mother, since he cannot stand, talk or feed himself nor can he control his bowels or bladder.

Such are the problems of parents and, in some cases, of lone mothers of the defective children of the Commonwealth

* * *

A realistic approach to the problem high lighted by this limited report brings sharply before one the need of substantially increasing the present resources, in terms of additional state institutions for custodial care, which maintain standards offering security both to the children placed therein and to their parents.

This provision for care might well, from an economic, as well as a social, humanitarian point of view include expansion of the present instructive and supervisory service already instituted by the Massachusetts Department of Mental Health for aid to parents in the management and care of defective children in their homes.

In this connection, the medical social workers believe that substantial help in meeting these admitted needs regarding care can probably be derived from earlier and more deliberate consideration of individual needs. The anxious and often seriously troubled parent may become more deeply disturbed by insistence that the infant should not be cared for at home, especially when it proves impossible to find a placement immediately. Experience has shown that in certain cases the defective child, far from being a monstrous object, can remain within the home at least for a time without disruption of the family, and even with greater ease of mind for the parents than if separation were effected from birth. It has been learned by the medical social worker that the mother who has been told not to see her newborn, defective baby visualizes something much worse than is really the case. Careful study and individualization in many cases, with the assistance of the social worker, would result in a more selective use of the limited resources, and in some cases might give greater help to parents in what is so often one of the greatest human problems.

CLINICAL NOTE

THE POSSIBLE INTER-RELATION OF
PSORIASIS AND *STREPTOCOCCUS*
FAECALIS

JACOB H. SWARTZ, M.D.*

BOSTON

MUCH has been learned about psoriasis, but none of the numerous theories have been substantiated by evidence that warrants a definite conclusion concerning its etiology.

Of particular interest is the fact that some cases have responded temporarily to a diet low in proteins, others to one low in carbohydrates, and still others to a low-fat intake. In many cases, however, if the patient continued on such a diet for any length of time, the improvement ceased. A change to another type of diet frequently resulted in further improvement.

It is noteworthy that there is a strong family history of psoriasis in a large group of psoriatic patients. This is also true of allergic diseases. Furthermore, Madden's¹ histologic studies of uninvolved skin of patients with psoriasis suggest a skin deviating from the normal in such cases. Both the above findings lead one to believe that psoriatic subjects may be born with a congenitally susceptible skin, which may become sensitized to the products of one or more organisms in the lower bowel.

The finding of a low redundant colon by barium enema in a small group of psoriatic patients studied, although not conclusive, suggests the stagnation and piling up of certain organisms in the lower bowel. Further studies in a larger series are necessary. Although no definite history of constipation was obtained, the following is a characteristic answer: "Shortly after a bowel movement, I feel that I could move my bowels again."

While investigating the presence of bacterial allergy in dermatitis herpetiformis, it was noted in some of the psoriatic patients used as controls that the intradermal injection of an autogenous stool vaccine brought on an aggravation of the psoriasis and a psoriatic lesion at the point of injection. The latter was thought to be Koebner's phenomenon,[†] but the exacerbation of a pre-existing psoriasis could not be so explained. By a process of elimination it was discovered that *Streptococcus faecalis* was the only organism in the stool that caused such reactions in psoriasis. Although this organism was almost always found in the stools of normal white persons, it was believed that the psoriatic lesions were possibly produced by a dilated colon favoring stagnation and a piling up of *Str faecalis* in those

born with a congenitally susceptible skin that had become sensitized to the products of this organism.

In a series of 15 cases, the intradermal administration of *Str faecalis* vaccine in proper dosage sometimes resulted in marked to moderate improvement, when too large a dose was administered, the patient was made definitely worse. In several cases a psoriatic lesion appeared at the site of injection following the undesirably large local reaction caused by a big dose. In 2 cases, swelling and pain of the phalangeal joints was associated with such doses. In 1 case, control injections of sterile water, saline solution and typhoid vaccine failed to cause such reaction.

It is my belief that there are strains of *Str faecalis* of different virulence, and that the most successful treatment with vaccine occurs when it is made from one of the less virulent strains, so that the patient can be desensitized without an untoward reaction. This belief is based on the fact that in the same subject the reaction varied with the amount and with vaccines prepared from various strains obtained from the stools. This method of treatment is not advised until further knowledge of strain and dosage has been obtained.

Another interesting point is that King² has reported that in the bacteriologic examination of consecutive stools of 14 full-blooded Negroes in an Army camp, no *Str faecalis* was found, whereas it was encountered in the stool of a mulatto. This finding appears to coincide with the fact that most Negroes do not suffer from psoriasis.

The above observations strongly suggest that the presence of a redundant colon results in an accumulation of *Str faecalis* in the bowel and that the development of sensitivity to this organism causes psoriatic lesions in a congenitally susceptible skin.

Externally applied therapeutic factors, such as ultraviolet light, ointments and the like, presumably decrease the sensitivity of the skin to the products of *Str faecalis*, at least temporarily. The remissions so characteristic of psoriasis may be explained on the basis of improved intestinal function, due in turn to seasonal changes in diet, outdoor exercise and so forth, or to unknown factors that at times so mysteriously influence the severity of other diseases of allergy, such as hay fever, asthma and angioneurotic edema.

The occasional case that is benefited by repeated transfusions of whole blood may be explained on the basis of the introduction of antibodies for *Str faecalis*.

SUMMARY

On the basis of the two following observations it seems likely that *Streptococcus faecalis* has some causal relation to psoriasis: marked sensitivity to intradermal injections of minute amounts of an autogenous vaccine made from a certain strain of

*Assistant professor of dermatology, Harvard Medical School dermatologist, Massachusetts General Hospital.

†This term simply signifies susceptibility to psoriasis in skin areas previously traumatized.

Sir faecalis in patients with psoriasis was demonstrated, both by a local reaction to the point of producing a psoriatic lesion and by an aggravation of the pre-existing psoriasis, and in the bacteriologic examination of the stools of full-blooded Negroes, most of whom do not suffer from psoriasis, *Sir faecalis* was not found

Intradermal injections with autogenous vaccines of *Sir faecalis* in proper doses for the given case, caused improvement of psoriasis, whereas a slightly

larger dose brought on an aggravation of the symptoms. Such treatment, however, is not advised until further studies have been made and the beneficial effects from proper doses have been evaluated

MEDICAL PROGRESS

PROCTOLOGY

E PARKER HAYDEN, M D,* AND THAD A KROLICKI, M D†

BOSTON, MASSACHUSETTS, AND PAWTUCKET, RHODE ISLAND

THE diagnosis and treatment of most diseases of the anus, rectum and colon have become fairly standardized over a period of years. Good therapeutic results can be obtained by careful attention to detail in history taking, examination, operative procedures and aftercare. A diagnosis can often be made on the history alone, although many serious mistakes have also occurred because of reliance on the history to the exclusion of a thorough examination by index finger, anoscope, sigmoidoscope and x-ray.

The cardinal symptoms of bleeding, pain, swelling, itching and disturbance of the normal bowel habits of the patient in question constitute the basis for a careful questioning, which will usually strongly suggest the diagnosis, easily confirmed in most cases by the standard methods of examination.

Refinements in technic, measures for the relief of pain, variations in the method of treatment and a few really new and promising suggestions are to be found in the literature of the past two years, a summary of which is presented in this review.

Rectal Bleeding

Bleeding from the bowel is perhaps the most important symptom that one is called on to explain, because its source may be relatively harmless or most serious.

Stone¹ has reported 72 cases of massive melena of obscure origin, with suggestions concerning procedure. This group consisted of 31 cases in which no cause of the hemorrhage could be found, 20 in which a possible source was located, and 21 others in which the source of bleeding was proved.

In the last group were included cases of carcinoma of the colon, carcinoma of the cardia of stomach,

cirrhosis of the liver with portal thrombosis, esophageal varices, subacute gastroenteritis, gastric ulcer, cyst and diverticulum of the duodenum, regional ileitis, Meckel's diverticulum, rupture of an artery in the rectal wall, lymphoid and myeloid leukemia and hemophilia.

In the group of 20 cases with unproved sources of hemorrhage the following conditions were also included: polyps of the colon, hypertension with arteriosclerosis, granuloma of the cecum, diverticulosis of the colon, esophageal hernia and diverticulum of the esophagus.

Stone emphasizes the importance of avoiding premature surgery, treatment for shock and hemorrhage, building up of the patient's general condition and careful search for the source of the bleeding as soon as it is safe to do so. When the source is definite, operation is indicated. Some cases never bled again, several after long intervals, and others at frequent intervals.

In the discussion of Stone's paper mention was made of two other possible sources — the so-called "red stomach," encountered in cases of cholecystitis, and bleeding due to a reduction in the coagulation time of blood by large doses of aspirin.

It is worthwhile to mention the fact that a massive hemorrhage may also occasionally be due to bleeding upward from internal hemorrhoids, with accumulation of blood in the rectum and colon until its volume produces expulsion in quantity. Rarely, a fissure may bleed profusely.

ANORECTAL PAIN

Preoperative anorectal pain is usually due to fissure, abscess or external hemorrhoidal thrombosis. Less often a low cancer, a foreign body or rectal spasm may be the cause. The cure lies in operation, except in the case of rectal spasm.

*Associate visiting surgeon, Massachusetts General Hospital.

†Surgeon, Outpatient Department, Memorial Hospital, Pawtucket, Rhode Island.

Postoperative pain is a different problem, and various suggestions concerning prevention and alleviation have been advanced

Pruitt² emphasizes gentleness in examination and manipulation, good lubrication, proper preoperative cleansing of the bowel, the use of a nonirritating enema (plain water or a soda or saline solution — *not* soap), the use of sulfonamide drugs to reduce acute inflammatory lesions and warm sitz baths as general measures designed to reduce pain. The use of drugs injected to give prolonged anesthesia of the area is advocated if judiciously applied. Pruitt mentions the various oil-soluble anesthetics, and also quinine and urea hydrochloride, Diothane, Nupercaine and alcohol. He cautions against the delay in healing that may occasionally result, with sloughing of the tissues, abscess formation and temporary incontinence. He particularly advocates 20 per cent ethyl alcohol in water, injected in the external sphincter through perianal punctures 5 or 6 mm apart all around the circumference, about 0.3 cc being used at each point. This is done before operation, under anesthesia, and it produces anesthesia of the local area for a period of a few days to two weeks. Elimination of sphincter spasm is a big factor in the relief of pain in addition to the anesthesia produced.

Smith,³ at the Mayo Clinic, points out the needlessness of anal dilatation as a preliminary to operations low in the rectum, and cites the disadvantages inherent in the procedure, namely, edema, extravasation of blood and external bleeding.

T. E. Smith⁴ reports the use, in 522 cases, of an anesthetic solution consisting of 6 per cent butyn, 1.5 per cent procaine hydrochloride and 5 per cent alcohol in a base of sweet almond oil. Injections, averaging 20 cc, were made deeply into the ischio-rectal fossa, with care to avoid pooling of the solution and with great care to maintain asepsis. Morphine was not needed postoperatively in 62 per cent of 250 cases, and in 54 per cent of 133 cases catheterization was unnecessary.

Pruitt⁵ discusses the condition known as "rectal cramp" or "rectal spasm" encountered at intervals in one's practice, usually unassociated with any demonstrable anorectal pathology but accurately described by enough patients to warrant its inclusion as a clinical entity. The pain is spasmodic, nocturnal as a rule, high in the rectum and lasts from a few minutes to half an hour. It is a gripping pain, quite severe, and comes on and disappears spontaneously. Relief may be obtained by changes in position, walking, rubbing, hot baths or warm enemas.

BLADDER DYSFUNCTION

McCrae⁶ discusses the urinary symptoms and urinary dysfunction associated with anorectal disease or following anorectal surgery.

There have been many suggestions offered to combat this frequent postoperative complication, among them the suggestion of the instillation into the bladder of 30 cc of mercurochrome while the patient is still on the operating table. Another is the ingestion of beer as soon as fluids are permitted postoperatively. Despite the employment of these measures routinely, most patients are subjected to catheterization before relief is obtained. The author suggests the following management preoperatively, the oral administration of 100 mg of Syntropan, followed postoperatively by the oral administration of 100 mg of Syntropan in combination with 15 mg of Prostigmine. The theory prompting such medication is that the Syntropan, acting directly on the sympathetic system, has some influence on the pudendal nerve, which undoubtedly contains sympathetic fibers or some communication to the sympathetic nerve in the establishment of a reflex arc, or that there is a direct communication, which is known to occur frequently between the inferior hemorrhoidal nerve and the pudendal nerve. The Syntropan exerts a sedative influence on the sympathetic nerves, whereas the Prostigmine increases the tonus of the detrusor muscle through the parasympathetic fibers, with the usual result of normal urination. This type of management has not been successful in every case, and no such claim has been made. One reason for failure, he believes, has been timidity in the administration of sufficiently large doses of Syntropan to establish a therapeutic effect. As experience grows, he believes that failures will be fewer in number. Much of the therapeutic action of these two synthetic drugs is pure conjecture. In their clinical use, however, the many remarkable results attained have suggested other possibilities in the management of certain types of "cord bladders." Plans have been laid to do considerable animal research on the action of these drugs in the presence of bladder dysfunction of neurogenic origin. Retention of urine following proctosigmoidectomy is of common occurrence, the retention being due to atony of the detrusor muscle resulting from trauma or severance of the parasympathetic nerve fibers. The best management of this type of retention is attained with the use of tidal drainage, which passively exercises the detrusor muscle, bathes the vesical mucosa continuously with bactericidal solutions, thus combating infection, completely eliminates residual urine and prevents renal back pressure. Following the use of tidal drainage, active therapeutic measures are essential. Parasympathetic stimulation of the detrusor muscle on the one hand and its sympathetic sedation on the other tend to produce normal urination. Acute urinary retention following anal surgery may also be successfully combated by the oral administration of Syntropan and Prostigmine in combination.

Pruritus Ani

Pruritus ani is one of the most frequent of all the anal ailments, and it certainly is the most difficult to treat satisfactorily. Attempts to establish any of the other common pathologic conditions in this area as etiologic factors in the itching have been notoriously unsuccessful. Treatment has been largely symptomatic consisting of ointments, washes, the injection of local anesthetic agents (usually in an oil medium to produce prolonged effect), alcohol injections and x-ray therapy.

Boyd and Bellows⁷ report therapeutic results obtained by means of an absorption-base ointment in 50 patients suffering from anorectal diseases. The purpose prompting this paper was to direct attention to a promising pharmacologic principle—the enhancement of drug action by the medium in which it acts. Although this fact is well known and widely applied by dermatologists, it does not seem to have engaged the attention of other physicians. For a long time dermatologists studied the penetrability and absorptivity of the skin, but progress was slow and sporadic so long as the basic materials for achieving these objectives consisted of a few fats and oils, in addition, the knowledge of surface chemistry was rudimentary. The irritation produced by many potentially useful agents precluded their application. Diseases of the anorectal region permit observations of the skin and mucous membrane, and a preparation has been formulated on the basis of the principle stated above.

The ointment in question consists of lanolin and cholesterol, with 2 per cent of cetyl alcohol and a wetting agent. As stated above, such bases characteristically improve absorption and penetration of the incorporated agents. The oil phase of the preparation consists of the oils of thyme and eucalyptus, whereas the water phase is represented by the fluid extracts of hamamelis and of krameria.

The pharmacologic action of the ingredients is universally known and requires no description. In addition to the astringent witch hazel and the tannin contained in the krameria, ephedrine was included for hemostasis. Local analgesia is secured by two common anesthetics, benzocaine and chlorbutanol. An antipruritic action is obtained by the oils previously mentioned and by camphor and menthol. Since infection may play a significant part in rectal pathology, an attempt has been made to diminish it by the inclusion of zinc oxide, titanium dioxide, chlorthymol and propyl para-hydro-benzoate. The solids are present in a highly subdivided form, they are not absorbed but are deposited on the surface as a protective screen.

The results were particularly satisfactory in the patients with pruritus ani. A fair number were relieved over a period of months. It was the author's strong impression that the results were most permanent in the group of cases considered to be due to

fungus infections. Accordingly, it appears likely that dual-purpose ointments will prove to be effective in the management of pruritus ani that is of infectious origin. The use of suitable bases to permit proper absorption of anesthetic agents and to suspend insoluble particulate antiseptics for deposit on the infected surface is desirable.

In this connection it is interesting to note that 5 per cent benzocaine usually afforded adequate analgesia in the absence of a fissure. This may be attributed to the absorption base, for without it the concentration of benzocaine required for relief is often in excess of 5 per cent, that is, in concentrations frequently causing irritation.

The relief afforded in nonfungus pruritus ani was also obvious, but observation over a long period will be necessary to determine the final outcome in resistant patients with no demonstrable etiology. The same holds true for the other subjective symptoms (burning, smarting and fullness). The inclusion, however, of many patients with chronic disease who had applied various preparations with indifferent success inclines the authors to believe that their claims of relief have considerable value.

It was difficult to evaluate the objective results except in cases of pruritus ani, where the effect on the skin could be visualized.

Hemorrhoids

Yaker⁸ strengthens the thesis that there is no reason for arguing whether surgical removal or the injection of sclerosing agents is the better form of therapy for internal hemorrhoids. He believes that there is ample reason for utilizing both methods, since good results are obtained by each. The essential thing is to recognize the fact that injection treatment should be chiefly reserved for uncomplicated and moderate internal hemorrhoids, whereas the so-called "mixed type" and the advanced cases should usually be operated on.

Whitney and Angelo⁹ list in order of importance what they believe to be the essential points in diminishing postoperative pain following hemorrhoidectomy: posterior incision of the sphincter or pecten band, the use of oil anesthesia, the placing of all sutures above the mucocutaneous line, clean-cut surgery, successful preoperative and postoperative narcosis, regional, spinal or caudal anesthesia, intelligent postoperative dressings, the prevention of complications, and intelligent management of the postoperative stool.

Inflammability of Intestinal Gases

The boyhood trick of igniting a burst of flatus with a lighted match held near the seat of the trousers at the proper moment has been brought to mind again—although probably not intentionally—by Liebermann,¹⁰ who reports a case in which an intrarectal explosion occurred during fulguration

of a polyp Hydrogen and methane are the gases responsible for this startling phenomenon, and it is recommended that after introduction of a proctoscope a stream of air be passed into the rectum and out again before the use of an electric spark

Deodorant for Colostomies

Carroll¹¹ suggests the use of enteric-coated capsules containing treated and activated carbon (90 per cent) and phenyl salicylate (10 per cent) orally two or three times a day There are no untoward effects, and the results are said to be good

Condylomas

Culp and Kaplan¹² report 200 cases of acuminate condylomas treated by podophyllin with remarkable results It appears that this drug may be considered almost a specific for the disease

Podophyllin is a powder that varies in color from light brown to greenish yellow and turns darker when subjected to heat and light It is an irritant and an active purgative A 25 per cent suspension in mineral oil has proved most efficacious in the treatment of anal warts The suspension is applied with a cotton swab to the surface of the lesions This is a painless procedure, and there is no immediate reaction In a few hours the growth becomes blanched, and in twenty-four or forty-eight hours necrotic On the second or third day it begins to slough, but the adjoining normal tissue is unaffected

No certain explanation of this more or less specific action of podophyllin is possible, but a logical assumption is that the irritating power of the drug produces spasm of the small vessels, which in turn causes ischemia, necrosis and sloughing Some dehydration also seems to occur

Speare¹³ at the Proctological Clinic of the Massachusetts General Hospital, has also been using this form of treatment with success

Imperforate Anus

Wilkinson¹⁴ mentions the difficulty in determining the precise method of treatment in cases of imperforate anus in babies because of difficulty in knowing just how far above the anal skin the end of the bowel lies A low rectum, with visible bluish bulging of the retained meconium, demands only a simple incision, whereas a higher-lying bowel necessitates much more of an operation He mentions the method suggested by Wangenstein and Rice¹⁵ of x-raying the infant suspended by its feet, to allow the rectal gas to rise to the blind end of the bowel, where it can be detected in relation to a metal marker placed on the perineum Ladd and Gross¹⁶ point out, however, that gas in the bowel often does not develop to a degree that makes this method of value until fifteen to twenty hours after birth

Foreign Bodies and Injuries

Yet another bit of evidence, if it is needed, of the toughness of the British is a report by Alkako-yunlu¹⁷ of the passage by rectum of a Kocher artery forceps left in the abdomen fourteen months previously in the course of a gynecological operation The patient began to have some vague symptoms six months prior to expulsion of the clamp, but the actual delivery was attended by no complications

Reports continue to appear from time to time, as they have over the years, of misguided persons who insert various foreign bodies in the rectum either to induce defecation or for some less wholesome reason The latest object in our experience was an olive bottle, intended to stimulate an evacuation of the bowels

Not long ago, one of us (E P H) operated on a boy who had impaled himself accidentally on one of the vertical wooden rods in the back of a chair of the Windsor type that had no curved top piece on it, being in process of repair This stick, 12 mm in diameter, was driven through the sphincter just at the left of, and parallel to, the rectum for a distance of about 15 cm until its tip was easily palpable under the skin of the left groin It broke off flush with the anal skin Catheterization revealed no blood in the urine, and laparotomy showed no intraperitoneal injury but a huge hematoma that dissected across the entire pelvis, raising up the peritoneum over the bladder half way to the umbilicus, presumably due to injury of the left deep epigastric vessels The midline wound was sutured without drainage, a small incision made in the left groin over the end of the stick, which proved to be just beneath the internal oblique muscle, and the stick was pulled out in two pieces from above Convalescence was marked by some fever, controlled by penicillin, and profuse drainage from above and below Several months later, with the perianal wound still draining slightly, an exploration from below brought forth another small piece of wood, which it is hoped will prove to be the last

Bendit,¹⁸ in reporting a case of injury to the rectum following an enema, cites Gabriel and Bacon as authorities for the statement that such injuries are more frequent than is generally realized The relative lack of sensation above the mucocutaneous line makes it possible to perforate the bowel above this point without much pain This particular patient, a man of forty-nine, in a hospital for treatment for hemorrhage from an ulcer, developed abdominal pain five days after an enema, and a perforation was found just inside the anus He recovered in seven weeks, after some perianal infection and foul discharge Sulfathiazole and gas-bacillus antitoxin were used

War wounds of the abdomen, buttocks and rectum itself have been fairly numerous, and colostomies have been done freely in these cases in Army and

Navv hospitals because of a conviction that this measure is the surest and safest way to reduce infection and to prepare the patient for later reconstructive surgery. In a visit to one of these hospitals we have seen a large group of patients whose colostomies seemed to be causing them no concern, if one can judge by appearances.

Prolapse

Skinner and Duncan¹⁹ suggest still another surgical procedure for the treatment of complete rectal prolapse. Many types of operations have been utilized with varying success in this condition, which is primarily a herniation of the cul-de-sac of Douglas. Operative procedures now in use are based on one or more of three principles: narrowing of the anus and rectum, suspension and fixation of the rectum, and resection of the prolapsed bowel.

These authors report 3 cases treated by an operation which is carried out in the following manner. The patient is hospitalized for three or four days for cleansing of the bowel, being placed on a low-residue diet. Under spinal anesthesia, in the Trendelenburg position, the abdomen is opened through a low rectus incision and the sigmoid is pulled taut. The peritoneum is then incised on each side of the mesosigmoid and is reflected laterally to expose the ureters, and the rectum is then freed from the hollow of the sacrum down to the coccyx by finger dissection. Care is taken not to injure the hemorrhoidal vessels. With the rectum pulled taut the reflected flaps of peritoneum are then sutured around the bowel, converting the previously deep cul-de-sac into a high-level pelvic floor. A temporary loop colostomy is then performed, using a glass rod. The patient remains in the hospital two weeks, and the colostomy is later closed. The authors acknowledge priority in this procedure, however, to Pemberton and Stalker,²⁰ who reported a similar operation in 1939.

Fistula

No recent article on the subject of anal fistula seems to add anything to the accepted principles of treatment of this condition. Over the years numerous attempts at primary closure of the excision wounds have been made, generally with little success. The pulling down of a cuff of intact mucosa over the internal opening after dissecting upward beneath the mucosa above it has been suggested. The best results have always come from the simple incision-and-drainage procedures, in which a few cardinal principles should be observed. Location of the internal opening is the crux of the whole situation, of course, and the main sinus tract is incised from this opening to the nearest external opening. There is no virtue in excision of sinuses as against free incision and curettage of the unhealthy granulations lining the sinus tracts. Elimination of over-

hanging wound edges, consistent with reasonable conservatism with respect to removal of vital perianal skin, and elimination of overhanging hemorrhoids adjacent to the internal opening make for a smooth convalescence and rapid healing. Good aftercare prevents bridging of the wound surfaces and consequent recurrence.

Fissure

Buxton²¹ outlines the principles in surgical treatment of anal fissure that he believes give the best results. These are as follows: excision of the fissure and sentinel pile, division of the external sphincter and postoperative mineral oil, antispasmodics, hot sitz baths, and finger insertion at intervals for two or three weeks. Most surgeons would agree with these principles, except that complete division of the sphincter, although perhaps the surest procedure, is not necessary in most cases. A division of the scar tissue superficial to the sphincter, together with a few of the superficial fibers of the muscle itself, is usually quite adequate.

Pilonidal Cysts and Sinuses

The requirement of the armed forces that soldiers and sailors shall be so treated as to ensure a minimum loss of time from active duty, as well as the high incidence of pilonidal disease, has brought this subject to the forefront of the problems of Army and Navy hospitals. The old argument of open operation versus primary closure has been revived everywhere.

Peterson and Ames²² describe an operation that is a compromise, and mention a few points of interest in connection with pilonidal disease. They state that the incidence of pilonidal sinus is three times higher in males than in females of the age group of greatest usefulness for military service. It is rare in the Negro and American Indian and has not been described in the Mongolian race. These structures are best defined as epithelial-lined sinuses of congenital origin occurring over the sacrococcygeal region, superficial to the bone and in or adjacent to the midline. There are three theories of origin: invagination of the surface epithelium, remnants of the obliterated neural canal, and an analogue of Preen's glands in birds. The general trends in treatment are based on complete removal or eradication of the sinus and tracts and on preoperative care and treatment of the infection. None of the operations in common use, however, satisfactorily prevent recurrences or long hospitalization in the majority of cases. The nature of the origin of the sinus provided a clue to a simple and certain method of treatment. The operation can be carried out without a long preoperative stay on the sick list and can be carried out aboard any ship, with only about three days lost from duty. It consists in thorough opening of the cyst and tracts, with mar-

supialization of the cyst wall to fill the defect. It can be carried out in the presence of heavy infection. Bleeding is minimal, no spread of infection occurs and healing is rapid and relatively painless.

Barker and Clark,²³ in 19 cases of chronic pilonidal infection, made an elliptical incision, undermined the lateral areas and did a primary closure with nylon mattress sutures tied over buttons, after placing 5 gm. of sulfanilamide powder in the wound and over its edges. The sutures are not tied over gauze, so that the incision can be dressed frequently for cleanliness. There was only one failure in this group, but no mention is made of length of the follow-up period. The average hospital stay was about twenty days.

Rogers²⁴ has struck a sensible note regarding the treatment of this disease in the Army and Navy. Most surgeons are agreed that excision and open packing is the best insurance against recurrence. Nevertheless, because of the long convalescence before complete healing, and because of Army insistence on hospitalization until healing is complete, many methods of primary suture have been devised, there has been some success, but often the results are based on incomplete follow-up data. Rogers says, "Why operate at all on many of these cysts and sinuses?" The disease is trivial, annoyance is usually slight, and the occasional abscess can be simply drained, often with months of complete or almost complete freedom of symptoms before another develops. This point of view, he adds, relates not to civilian but to military practice, where conservative measures have much to recommend them.

Magrath²⁵ believes that the present appellation of pilonidal or sacrococcygeal cyst or sinus is unsatisfactory and that the present statistical method of reporting end results of operative procedure is misleading. Under the present system of general inclusiveness, one series of cases may present such extraordinary end results that a surgeon may attempt the same type of operation in an entirely different type of involvement, with discouraging results. He is thus influenced in discarding a perfectly good means of treating another type of disorder. Magrath believes that an accurate appellation may serve to clarify the controversial issue between packing the extirpated area to heal from the bottom up or closing to heal by primary union, thus permitting a better estimation of operative end results.

Barnett²⁶ states that military expediency demands a method of treating pilonidal cysts that requires little postoperative care and furnishes a well healed, protective scar. He believes that the recently developed technics of excision and primary closure in selected cases, in conjunction with sulfonamide therapy, offer the best solution of this problem. The more conservative method of excision and open packing, however, is indicated in many cases not

amenable to closure, and in civilian practice, it is the procedure of choice.

Stricture

Woods and Hanlon²⁷ review the general problem of inflammatory stricture and present an analysis of 192 cases over a twenty-five-year period at the Cincinnati General Hospital. They accept the generally conceded fact that the origin of these strictures lies in the disease, lymphopathia venereum, and they mention the numerous and unsatisfactory methods of treatment.

A positive Frei test was obtained in 86 per cent of 105 cases. The microscopic picture, when observed, was always that of nonspecific inflammation.

In this series, 108 patients were dilated one or more times under anesthesia. There were 4 deaths from peritonitis and 2 from shock following this procedure. Eleven patients died as a direct result of the disease at periods up to thirteen years. In a follow-up on 77 of these cases, of which 32 were mild and 45 severe, no really good results were obtained.

Colostomy produced improvement in symptoms and general condition in 41 patients. Abdominoperineal resection was done in 23 cases, and the one-stage method was employed in 16, with good results. The authors decided, however, that the two-stage method of Lahey is preferable, since it provides a colostomy, with the bowel prepared for resection at any time thereafter if deemed necessary. Resection, by one of several methods, was carried out in 35 cases without a death.

The authors condemn dilatation under anesthesia because of its dangers, and conclude that colostomy and sulfonamides make resection of the rectum unnecessary in the majority of cases.

Megacolon

McKell²⁸ reports the cases of 3 patients, aged four, four and eleven, with congenital megacolon who were treated with Prostigmine after first having a daily bouginage of the anus for three weeks to relax the contracted sphincter. These children, who had been evacuating their colons at intervals of four to seven days, were made to have daily stools. The Prostigmine dosage was 5 mg. three times a day, 0.5 mg. of ergotamine tartrate also being given to one of the children. In one case the old bowel habits returned after discontinuance of the drug, whereas in the others a daily evacuation was still being obtained one and five weeks, respectively, after cessation of treatment. The follow-up data are, of course, too short to be of value.

Whitehouse, Bagen and Dixon²⁹ reviewed 29 cases of congenital megacolon in children in whom subtotal colectomy was performed between 1909 and 1941. All were definitely classified as having Hirschsprung's disease. They consider this to be the method

of choice when medical measures and sympathectomy have proved unsuccessful

Acute Ulcerative Colitis

Sulzberger³⁰ presents a single case of acute ulcerative colitis that was thoroughly studied. This type of case, which is seen at intervals by those who have contact with many cases of idiopathic chronic ulcerative colitis, is an extremely serious problem. A large tender spleen, swelling of a knee joint, erythema nodosum and lack of response to ileostomy or to penicillin, with death from multiple perforations of the colon, were the striking features in this case. Only after use of sulfadiazine did apparent improvement occur, but this was of short duration.

Whitby,³¹ in an article on the choice and use of sulfonamides, states that sulfaguanidine is the drug of choice in the treatment of bacillary dysentery of the Flexner type. In adults, it is advocated in dosage of 9 to 12 gm daily for three days, followed by 6 gm daily for four or five days. Succinyl sulfathiazole is said to be more active against dysentery of the Sonne type.

Regional Segmental Colitis

Barbosa, Barga, and Dixon³² carried out a statistical study of 140 cases of regional segmental colitis seen at the Mayo Clinic over a twenty-year period. The etiology is unknown. The series includes only those cases which, when first seen, had no involvement of the rectum, differing thereby from the usual case of chronic ulcerative colitis. The great majority also showed no evidence of terminal ileitis, although a few patients (18 per cent) developed it as an extension from the cecum. This group of 140 cases comprised 4 per cent of cases of ulcerative colitis of all types.

It was impossible to classify the cases anatomically because of the wide variation in location and in the extent of involvement, but in all cases in which surgical specimens were obtained, the microscopical picture was similar, corresponding to that seen in regional ileitis and in diffuse ulcerative colitis. In general, the right colon was oftener and more extensively involved than the left, in contrast with the findings in diffuse ulcerative colitis.

Symptoms varied greatly, but cramps were frequent and the stools usually contained little blood. Some patients were extremely sick, with fever and toxemia. Considerable loss of weight occurred.

The diagnosis is made almost entirely by x-ray examination, which reveals narrowing, hyper-irritability, shortening or loss of haustration in a segment of colon of a patient in whom proctoscopy shows normal mucosa in the rectum or possibly just the lower limits of the higher segment of colitis.

Of the 140 patients, 90 were treated medically, and 43 surgically, whereas 7 received no treatment. The incidence of recurrence following medical treat-

ment was higher than that following radical surgery, and the authors believe that complete removal of the diseased area is the best treatment. In this connection it is necessary to resect well beyond the area of obvious clinical involvement. Stippling of the serosa indicates disease in bowel that otherwise seems normal to inspection and palpation. Succinyl sulfathiazole preoperatively seemed to be of value in making resection safer.

Hardy,³³ in a lecture delivered before the Royal College of Physicians in London, gives his answer to some of the questions that have occurred to many others regarding the problems of colon neurosis and ulcerative colitis. His ideas (partly in summary and partly by direct quotation) are as follows:

Colon neurosis and ulcerative colitis are respectively the ultimate expression of disorder and disease as we see it in the colon, but there is no evidence whatever for regarding them as successive stages in the development of one disease process. Colon neurosis begins and ends as a neurosis, and it is quite exceptional to find evidence of inflammation in the stools or through the sigmoidoscope. Ulcerative colitis is a disease *sui generis* and develops along its own special lines. Only rarely is a previous history of colon disorder obtained. There are, however, certain resemblances between the two disorders. In both the functions of the bowel are exaggerated. Only in one are there superadded the exudative manifestations of inflammatory disease. Psychological events are prominent in the history of each, and there is a close association between emotional episodes and bowel upset, but I have not recognized any special type of individual in colon neurosis, at least not so consistently as the immature personality in which the graver disorder seems to thrive. Age-incidence may have something to do with this condition, for colon neurosis tends to fall about a decade later. Other psychosomatic disorders, such as asthma, peptic ulcer, and Graves's disease, are wont to be associated with colon neurosis but not with ulcerative colitis.

When we come to consider the mechanisms that determine the ultimate tissue reaction, we are on difficult ground. It would seem from experiments of Florey (1938) that the sacral autonomic system is the final common pathway whereby many extrinsic and intrinsic factors are translated into increased or abnormal activity, in the one case keeping within the borders of the normal pattern, and in the other uncontrolled, passing from disorder into disease with exudation, tissue necrosis and secondary invasion. That such a process can occur has been revealed in the work of Wolf and Wolff (1942) on peptic ulcer.

One can even recognize resemblances between peptic ulcer, especially duodenal ulcer, and ulcerative colitis — the ingravescent onset with dyspepsia in the one and diarrhoea in the other, the tendency for periods of quiescence to alternate with periods of activity and for these to be dependent on emotional influences, and the ultimate establishment of structural disease in both. We can recognize, too, similar milestones in the progress of each, more pronounced in the commoner and better known disease, yet discernible in the other — a period of environmental stress acting on a predisposed, or ultimately producing, a sensitive constitution, a period of intermittent exaggeration of function, a period when the abnormal function has become the conditioned and inevitable response to certain stimuli, and finally a period of irreversible structural change.

He concludes

In these lectures I have tried to illustrate the general principle that certain disorders and diseases, which, for the present, we speak of as psychosomatic have their origins not in any extraneous agency but in a perversion of normal function, and to suggest as a corollary that for inquiry to be fruitful and treatment effective the evolution of events — order, disorder, disease — must be fully appreciated.

The history of medical progress shows that advance is uneven, periods of great activity being punctuated by periods of stagnation during which ground won is consolidated. We are now at the end of a period which has been dominated by the ancillary sciences, notably radiology and biochemistry, and during which the individuality of the patient has suffered some eclipse. There is evidence now of a new sense of direction to study man not only in sickness but in health, in his home as well as in the hospital, to see at first hand those social, financial and industrial impacts which are his daily lot, to learn their influence in the initiation, aggravation and perpetuation of disease, and perchance to control them so that order shall not proceed to disorder, nor disorder to disease.

Carcinoma

Because of the large number of papers constantly appearing on the subject of carcinoma of the colon and rectum, their review is beyond the scope of this paper.

Adenoma

The importance of benign adenomas or mucous polyps as a cause of bleeding from the rectum in children is stressed by Kennedy, Dixon, and Weber,³⁴ who report 11 cases. In 6 of the 11 there were polyps in the rectum as well as higher up. For this reason the observation of polyps in the rectum should always suggest the desirability of a search by barium enemas for others beyond reach of the sigmoidoscope. The higher polyps were removed either by incision of the colon or by resection of a segment, as indicated.

Cooper and McDonald³⁵ have reviewed the literature in relation to the eccrine and apocrine sweat glands of the anal region, particularly regarding the tumors that originate in these glands. The apocrine glands, which are odoriferous, develop at maturity and can be considered as accessory sexual glands. One of the authors (McDonald), in 1941, described a neoplasm whose origin was definitely traced to an apocrine sweat gland of the vulva, and in the present article is reported what the authors believe to be the first case in the literature of a neoplasm of the anus arising from an apocrine sweat gland. A woman of forty-two, who was operated for gall stones, was found to have a small cyst just external to the anus. This was removed. It measured 1.5 cm in diameter, was covered with squamous epithelium and contained within it a papillary tumor made up of glands lined by eosinophilic cells that answered the description of those found in apocrine glands. A transition from normal to tumor cells could be observed, but there were no mitoses. The authors suggest a relation between

these tumors and intraductal papillomas of the breast, which resemble them closely and probably develop from similar glands.

CASE 31361

PRESENTATION OF CASE

A sixty-one-year-old woman was admitted to the hospital complaining of back pain.

Three weeks before admission she noted sharp nonradiating pain in about the middle portion of the thoracic spine. It became worse when she leaned over. Six days before admission the pain completely disappeared. The following day there were numbness and weakness in the lower extremities, but the patient was still able to walk. Thirty-six hours later she was unable to walk. The numbness and weakness became progressively worse. She became incontinent of urine, and enemas had to be given.

Twelve years before admission she had injured the sacrum and the lumbar region of the spine in a fall and was immobilized in a plaster cast for twelve days. She had had one miscarriage and one normal child.

Physical examination revealed a well developed and obese woman in no acute distress. The pupils were regular and equal, they reacted to accommodation but not to light. Examination of the heart and lungs was negative. The abdomen was distended. The bladder was palpated half way to the umbilicus, but she suffered no discomfort. The strength of the arms was good, and the tendon reflexes of the upper extremities were brisk and equal. The abdominal reflexes were weak, the left being less active than the right. The knee jerks were weak. There was no patellar or ankle clonus. The plantar reflexes were extensor on both sides. Sensations of pain and touch were impaired bilaterally, particularly on the right below the third thoracic segment. Vibration sense was decreased below the nipples. There was tenderness over the region of the sixth thoracic vertebra.

The temperature was 98.6°F, the pulse 85, and the respirations 20. The blood pressure was 150 systolic, 80 diastolic.

On admission the urine gave a + test for albumin and contained 10 red cells and 10 white cells per high-power field. Later specimens were negative. Examination of the blood on entry showed a red-

cell count of 4,350,000, with a hemoglobin of 80 per cent, and a white-cell count of 10,400, with 78 per cent neutrophils, 20 per cent lymphocytes and 2 per cent eosinophils. The nonprotein nitrogen was 30 mg per 100 cc, the total protein 6.6 gm, and the fasting blood sugar 102 mg. A rapid Hinton test was negative. A lumbar puncture yielded a small amount of slightly xanthochromic fluid under practically no pressure. There was no increase in pressure on jugular compression. The last portion of fluid was slightly bloody. It contained 2520 red cells, 3 polymorphonuclear cells and 4 lymphocytes per cubic millimeter. The gold-sol curve was 1455555554. The total protein was 1140 mg per 100 cc, and the sugar 38 mg.

X-ray examination showed the lung fields to be clear. The lateral portion of the left half of the diaphragm was somewhat elevated, and there was obliteration of the left costophrenic angle, without evidence of fluid or other definite pathology. The heart was slightly enlarged in the region of the left ventricle. The aorta was somewhat tortuous. Films of the dorsal spine showed some osteoporosis of all the visualized bones. All the pedicles were preserved, but there was slight decalcification of the left fifth, sixth and seventh dorsal vertebrae. The disk spaces were not remarkable.

On the first hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR WILLIAM SWEET: Perhaps this is as good a time as any to see the x-ray films.

DR MILFORD D. SCHULZ: There is some loss of contour of the posterior margins of the bodies of the fifth and six vertebrae. This segment shows a little decalcification, but certainly it is not pronounced. There is no definite evidence of bone destruction.

DR SWEET: The interpretation at the time the films were taken mentioned slight decalcification of the fifth, sixth and seventh dorsal vertebrae.

A transverse lesion of the spinal cord developing this sequence of symptoms and signs in a total duration of only three weeks is likeliest, on a statistical basis, to be due to a malignant neoplasm invading the spinal canal, but before we alight on that dismal diagnosis, we should consider a number of things that suggest other possibilities.

I might first go through the symptomatology to indicate how confident we can be that the patient had some sort of a space-taking lesion. The initial symptom of pain referred to the middle portion of the thoracic spine was presumably on the basis of irritation of one of the small branches of the intercostal nerve in that particular region and could have been due to a space-taking lesion, such as neoplasm, abscess or granuloma. The rapid development of involvement of the spinal cord, once the first symptom had occurred, suggests a neoplasm that was

*On leave of absence

malignant but does not rule out the possibility — perhaps makes it likelier — that there was frank pus or a granulomatous lesion. In cases of extradural neoplasm, following the evidence of irritation to nerve root, there is usually a period of weakness in the lower limbs before sphincter disturbance and sensory loss appear, but in this case the sensory loss and weakness appeared simultaneously, which suggests either a rapidly developing neoplasm or a granuloma. I do not believe that we can get any help from the past history. The history of injury to the lumbar spine and sacrum does not, to my mind, suggest any connection with the high thoracic lesion, and the history of one miscarriage and one normal child does not point to syphilis. We must pay more attention to the fact that the pupils reacted to accommodation but not to light. We are not told whether the pupils were small, that is, whether they corresponded to the Argyll-Robertson pupil in this respect.

DR CHARLES S KUBIK The pupils were 4 mm in diameter.

DR SWEET In other words, they were of fairly good size — not so miotic as many Argyll-Robertson pupils. The blood Hinton test was negative. We know, however, that approximately 5 to 10 per cent of the cases of parenchymatous neurosyphilis do not have positive serologic reactions in the blood but do have them in the spinal fluid. This patient apparently was such an emergency that there was not time enough to wait for serologic examination of the spinal fluid. So the facts that the pupils did not react to light and that there was no serologic examination of the fluid in which the reaction might well have been positive make me pay more attention to the likelihood of syphilis than I might otherwise do. I have never seen a case in which a rapidly developing transverse lesion of the spinal cord was due to syphilis, but I looked the subject up for my own instruction and was astounded to discover papers reporting a large number of cases in the first fifteen years of the century — one paper from England¹ and another from France² — in which syphilis was the most frequent disease to produce a rapidly developing transverse lesion in the spinal canal. The reason one does not see it so often nowadays is that the medical treatment of syphilis has made rapid strides. The x-ray films show only slight osteoporosis. If we are to pay attention to this minimal decalcification in the thoracic vertebrae then I think we should consider syphilis as rather unlikely. When syphilis invades the bone it is much likelier to produce extensive osteoblastic changes than a diffuse osteoporotic or osteolytic process. These bone changes are so slight, however, that we should not place too much weight on them and perhaps put more weight on the possibility that the patient had syphilis.

There are two reasons for paying attention to the diagnosis of epidural abscess. The symptoms were

of short duration, only three weeks, beginning with pain localized over a portion of the thoracic spine, which is typical for epidural abscess. The physical examination showed tenderness over the region of a thoracic vertebra, which is also typically seen in cases of epidural abscess. Against this possibility is the fact that there was not a decisive increase in the number of white cells in the spinal fluid. The fact that it contained 3 polymorphonuclear cells and 2500 red cells per cubic millimeter, a ratio of approximately 1 white cell to 1000 red cells, suggests that slight hemorrhage was responsible for the polymorphonuclear cells, and I do not believe that we can say that she had evidence in the spinal fluid to favor the diagnosis of epidural abscess. I do not believe, either, that we get a clue from the red cells in the spinal fluid to the type of lesion invading the spinal canal, because it is not infrequent for one to find a few red cells in the spinal fluid, particularly when there is complete block, with the result that the spinal fluid does not come out below the level of block so easily as it normally does. It is then easier for a nerve root to come against the needle point and to be slightly damaged by virtue thereof. The extremely high gold-sol figures are consistent with the high level of total protein, all of which simply indicate a severe Froin's syndrome and lend no support to the possibility that the patient had syphilitic disease. To rule out the hopeful diagnosis of epidural abscess, one might also mention the fact that there is nothing in the history to suggest a source of primary infection elsewhere in the body. The patient had a normal temperature and white-cell count and apparently was not systemically ill. I have seen cases of epidural abscess in which there was no evidence of a previous focus of infection, but they did not occur in people of this age. Hematogenous infection of the epidural space and of the bones is rare in people of this age group. Also, the type of bony lesion seen in the vertebrae does not favor the diagnosis of epidural abscess or vertebral osteomyelitis. After three weeks we might expect to see slight erosion or slight osteoporosis, but it is likely to be confined to a single vertebra rather than to involve two or three.

So it looks as though we were gradually converging on the diagnosis of a malignant neoplasm, and if we are to place any weight on erosion of three vertebral bodies, we can rule out all intramedullary and all intradural extramedullary space-taking lesions. I shall proceed to the extradural space-taking lesions.

Certainly these x-ray films are not at all characteristic of tuberculosis. There is no extensive destruction of the bone such as one usually sees in tuberculosis that is accompanied by sufficient granulomatous tissue in the spinal canal to produce spinal block. The fact that the patient has a normal x-ray film of the chest also helps one to disregard the diagnosis of tuberculosis.

The four sites in the body from which carcinoma is likeliest to metastasize to bone are the prostate, breast, thyroid gland and kidney. Some 30 per cent of metastatic carcinomas in the spine come from the prostate, and 25 per cent from the breast, ovaries or uterus, the breast being by far the most frequent of the latter. In this case, the prostate, of course, is excluded. Metastasis from cancer of the breast frequently shows osteoblastic increased bone density as well as osteoclastic decreased bone density in the vertebrae. The facts that there was no increased density and that physical examination of the breasts was normal assist us materially in ruling out this diagnosis. Carcinoma of the thyroid gland often produces metastases before the primary lesion is recognizable. The slight trace of albumin and the red cells in the urinary sediment may be a clue that the patient had a renal-cell tumor. The lungs and the gastrointestinal tract are other sites for primary tumors that metastasize to the spinal canal. Again, they may show in the spine before there is any evidence of the primary location.

As for primary vertebral tumors, osteogenic sarcoma and Ewing's tumor may virtually be ruled out. They occur by far and away more frequently in the long bones of children, so that the age of this patient and the location of the disease practically eliminate either possibility. All forms of lymphoblastoma are extremely unlikely, there were no enlarged lymph nodes, nor were there changes in the blood or fever. It is still possible, however, that a lymphoblastoma diffusely invaded the three vertebral bodies and produced this picture. Multiple myeloma should be considered, although in most other parts of the body it produces a more punched-out appearance in the bone than is seen in these vertebrae. Since it may produce diffuse vertebral rarefaction, it must be considered a definite diagnostic possibility.

Primary malignant tumors of the vertebrae are distinctly less frequent than is metastatic carcinoma, so that I shall say that the diagnosis is a metastatic carcinoma arising from either the thyroid gland, kidney, ovary or uterus or, less likely, from the lungs or the gastrointestinal tract. Even if the patient had syphilis it is likelier that the involvement of the spinal cord was due to neoplasm than to syphilitic disease.

DR. MADELAINE BROWN: I was on the visit when this patient was admitted. Dr. George C. Cotzias, the resident, made a diagnosis of syphilis, probably gumma. I believed that this diagnosis certainly was a possibility, but I thought that the lesion was probably an epidural abscess.

DR. KUBIK: On what did Dr. Cotzias base his diagnosis?

DR. BROWN: The Argyll-Robertson pupils.

DR. KUBIK: That, it seems to me, was the only finding suggestive of syphilis.

CLINICAL DIAGNOSIS

Gumma of spinal cord

DR. SWEET'S DIAGNOSIS

Epidural metastatic carcinoma of spinal canal

ANATOMICAL DIAGNOSIS

Epidural gumma of spinal cord

PATHOLOGICAL DISCUSSION

DR. KUBIK: I might say that Dr. Sweet was given the serologic findings that had been obtained up to the time of operation, that is, the report was based on a rapid Hinton test which was negative. After the operation, a regular blood Hinton test and a spinal-fluid Wassermann test were positive.

Laminectomy of the sixth to the tenth thoracic vertebrae exposed an epidural mass firmly adherent to the outer surface of the dura. Most of it was removed. It was found on microscopic examination to be a gumma. We have had only one other proved case that I can find. That patient was a thirty-three-year-old man with a paraplegia that had developed gradually over a period of five months. There was a block, as in the case today, and there were 112 cells per cubic millimeter of cerebrospinal fluid. The lesion was similar to what was found in this case. It was a sharply defined mass about 5 cm in length and 1.5 cm in width and 3 or 4 mm in thickness, it was firmly adherent to the dura but did not completely encircle it. There was cellular infiltration of the dura, but little or no reaction on the inner surface of the dura.

The symptoms in these cases are apparently due to compression by the extradural mass and not to syphilis of the spinal cord. In a case of rapidly progressive paralysis, surgical decompression is probably indicated, even if one could be sure of the diagnosis. One has to keep in mind that in a patient with syphilis or neurosyphilis an unrelated condition may be responsible for his symptoms. We have had cases of both spinal tumor and brain tumor in patients with syphilis.

Does anyone know what became of this patient?

DR. BROWN: She could move one leg for a while, but the next time that I saw her the legs were completely paralyzed. I do not know the final outcome.

CASE 31362

PRESENTATION OF CASE

A sixty-two-year-old painter was admitted to the hospital because of chest pain, cough and loss of weight.

Fifteen months before admission the patient complained of a slight amount of pain in the left chest, with cough, and at about the same time he noted

the onset of loss of appetite. Fourteen months before admission an x-ray examination allegedly showed an area of increased density in the apex of the left lung. The symptoms remained unchanged until about six weeks before admission, when the anorexia became more pronounced and the cough and chest pain more severe. He had not worked, however, for the previous six months because of the pain. He described a severe, constant ache centering in the left anterior chest, approximately over the third rib in the midclavicular line, it frequently radiated to the midline. In addition he experienced many times a day an excruciating knifelike pain that stabbed through the left chest into the region of the back between the scapulas. Cough, which had been present for many years, had recently become painful, more frequent and productive of a small amount of thick, white sputum, which never contained blood. Three weeks before admission an x-ray film of the chest had been taken in the Out Patient Department. This showed a large area of increased density in the left upper lobe. Two weeks later, bronchoscopy was negative. During the week before admission he had had night sweats and had slept but little because of pain. For many years he had had urgency and nocturia (twice).

Ten and a half years before admission the patient had a combined abdominoperineal resection for a large, Grade II adenocarcinoma of the rectosigmoid. He was discharged well in three weeks. A few days later he was readmitted and treated over a period of six weeks for cystitis and probably pyelonephritis.

Physical examination showed a well developed man, with evidence of recent weight loss. A moderately firm, nontender, freely movable nodule, measuring about 5 cm. in diameter, was felt in the left lobe of the thyroid gland, the rest of the gland was not palpable. The heart was normal in size, rate and rhythm, the sounds were somewhat distant. Chest expansion was normal and symmetrical. Except for an occasional wheeze over the left upper chest anteriorly, the chest was negative to auscultation, but there was an area of dullness over the left upper lobe posteriorly. The abdomen was normal, except for a well functioning colostomy stoma in the left lower quadrant. The extremities were normal. There was no clubbing of the fingers or toes.

The temperature, pulse and respirations were normal. The blood pressure was 130 systolic, 85 diastolic.

Examination of the urine was negative. Examination of the blood showed a white-cell count of 5900 and a hemoglobin of 85 per cent. The prothrombin time was 21 seconds (normal, 18 to 20 seconds).

X-ray examination of the chest showed a large area of density in the left upper lobe extending into the apex (Fig. 1). The left hilus was slightly elevated, and the septum between the lobes was some-

what high in the posterior portion. The left lower lung field and the right lung appeared clear.

On the eighth hospital day an operation was performed.

DIFFERENTIAL DIAGNOSIS

DR. REED HARWOOD. Before discussing the diagnosis in this case, I should like to comment on the x-ray films. The lesion at the left apex does not appear to be a solid mass or tumor; its density suggests a collapsed left upper lobe, and this is corroborated by the finding that the left hilus, the

FIGURE 1 Roentgenogram of Chest

interlobar septum and the left leaf of the diaphragm are slightly higher than normal. A large tumor in this region might be expected to produce hoarseness and a Horner's syndrome, neither of which was present. I believe, then, that the lesion in the left upper lobe is a small one that has produced obstruction to the left upper lobe bronchus.

Two diagnoses occur to me to warrant serious consideration: bronchiogenic carcinoma and pulmonary tuberculosis. A metastasis from the rectal carcinoma seems unlikely for several reasons: first, because of the long period of time since his operation; second, because of the absence of other metastatic lesions; and third, because such a lesion usually arises in the parenchyma of the lung and thus is not likely to produce bronchial obstruction. No one of these reasons alone is valid, but together they seem convincing evidence against this diagnosis.

Pulmonary tuberculosis with a constriction of the bronchus must be considered. In these exercises such a lesion has been too often overlooked. In favor of this diagnosis are the duration of the symptoms and the so-called "constitutional symptoms"—anorexia, weight loss and night sweats. There are several features against this diagnosis, however, the most significant of which is the character of the chest pain. In my experience, pain is rarely present in tuberculosis, except, of course, when there is an acute pleurisy. This patient's pain appears to have had no relation to respiration. The absence of disease in the other lung is also against tuberculosis. No mention is made of an examination of the sputum, if it was done, I assume that it was negative.

In this age group, the presence of unilateral wheeze and chest pain suggests most strongly the diagnosis of bronchiogenic carcinoma. It is not at all unusual for a patient to develop more than one type of cancer. I am a little disturbed that there is no history of hemoptysis, since this is such a frequent symptom. I believe, however, that its absence does not exclude the diagnosis. The character of the pain is a little unusual, especially the recently developed knifelike pain between the scapulas. Such a pain suggests that the tumor has invaded not only the pleura but also the adjacent bony structures, either a vertebra or a rib. In fact, close inspection of the x-ray films shows a suspicious area in the fifth rib near its vertebral articulation. Although the overlying diseased lung obscures its outlines, it seems probable that this rib was involved. Such an event would be an entirely adequate explanation of the excruciating pain that this patient experienced.

There are several types of benign tumor, especially neurofibroma, that erode ribs in this region. I believe, however, that the x-ray picture is not consistent with this diagnosis.

My final diagnosis is bronchiogenic carcinoma, with extension to the pleura and ribs.

CLINICAL DIAGNOSIS

Bronchiogenic carcinoma

DR HARWOOD'S DIAGNOSIS

Bronchiogenic carcinoma, with extension to pleura and rib

ANATOMICAL DIAGNOSIS

Epidermoid carcinoma (Grade III) of bronchus, with metastasis to regional lymph nodes

PATHOLOGICAL DISCUSSION

DR BENJAMIN CASTLEMAN: At operation, Dr Rodolfo Herrera found a small, indurated left upper lobe, with its apical segment firmly adherent to the chest wall at the apex of the chest cavity. An extra-pleural dissection was performed, but he thought that the tumor adherent to the chest wall was not completely removed. A pneumonectomy was then carried out.

The specimen revealed an apical, solid, spherical, gray-white, granular tumor about 7.5 cm in diameter.

FIGURE 2 Photograph of Cross Section of Left Lung

(Fig 2) It was traversed by the posterior superior division of the upper lobe bronchus and appeared to arise from it. The lingula was not involved. There was obvious involvement of the regional lymph nodes. Microscopically, it was a rapidly growing epidermoid carcinoma.

WAR'S END

THE war's end has come, not unexpectedly and yet with an abruptness that made it, at first, difficult to grasp, like consciousness returning to a sleeper after a bad dream or to a patient after anesthesia. The nightmare of strife through which we had been living seemed the totality of reality, without beginning and without end, relative peace seems now to be the world's normal status, and the years through which we have been passing an interlude of unreality.

So ends, like a fantasy, the greatest madness in man's history,—and may it be the last,—with all the world, save for a handful of small nations, in arms, with cities laid waste on a scale that would have

excited the envy of Joshua and with most of the servants of science and their devices turned toward the destruction of life and property. In one division alone—that of medicine—among the forces that were gathered to join the battle on the land and on the sea and in the air was modern ingenuity turned solely to the saving of life and the alleviation of suffering in friend and foe alike.

There was no alternative to our course, so far as our national obligations were concerned. A nation devoted to peace, we became committed to war, and only by making war our single purpose were we able to demonstrate that clear-cut superiority over our enemies that could end only in total victory.

We are proud that in this war the profession of medicine showed its indispensability, we are doubly proud that its military duty has always lain in the saving of life rather than in the taking of it and in the reconstruction of the human mind and body rather than in their destruction.

QUARANTINE BROUGHT UP TO DATE

OUR rules of quarantine, originally suggesting, as the word implies, a forty-day period of exclusion from the usual activities of mankind, have undergone periodic modification with increased knowledge of communicable diseases, with a decline in the severity of certain of these diseases and with improvement in the methods of control and treatment. Thus, certain of the so-called "diseases of childhood" with which we are currently acquainted have undergone natural modification in their severity within a lifetime—notably scarlet fever and measles, smallpox and diphtheria have become positively controllable, the one nearly a century and a half ago, and the other within a generation, whooping cough may be virtually controlled by the prophylactic use of vaccine, scarlet fever by immunization with toxin and by treatment with anti-toxin and the sulfonamide drugs, and measles through modification by the injection of immune globulin.

Dangerous as any disease may be in a specific case, there is no particular need for perpetuating the terror in which most of the communicable

diseases were originally held, or in continuing to accept the oppressive regulations that once encompassed them. In this relaxation of our rules of quarantine, the Massachusetts Department of Public Health has been a leading factor, modifying its regulations from time to time until now no exclusion from school is recommended for chicken pox, measles or rubella contacts and nonimmune scarlet-fever contacts are allowed to resume their academic pursuits as soon as the quarantine of the patient is removed — a minimum period of only three weeks.

Continued experience with the communicable diseases has shown that there is little occasion for any person to be afflicted with the more serious ones and has, on the whole, attested to the desirability of acquiring the others during the first decade of life. Practically everyone will agree to this principle regarding mumps, and recently reported evidence concerning the effect of maternal rubella on the fetus has shown dramatically the dangers that may be run by delaying the acquisition of this mild virus infection until adult life.

Our private schools, however, still show a distinct tendency to react with every evidence of incipient panic to the usual virus diseases with which their pupils may come in contact, although a more realistic attitude to adopt would be that of our experienced health authorities. Let the children have their exposures to chicken pox, to measles, to rubella and to mumps at a decently early age, and let them thus avoid the social and physical complications that are liable to accompany the acquisition of these infections during adolescence or in later life. It might be well, also, in the constant battle between education and communicable-disease control, to consider that education should win an occasional round.

MASSACHUSETTS MEDICAL SOCIETY

DEATHS

BUSHOLD — Fred G. Bushold, M.D., of Lawrence, died June 8. He was in his sixty-fifth year.

Dr. Bushold received his degree from Tufts College Medical School in 1904.

CABOT — Hugh Cabot, M.D., of Needham, died August 14 at Ellsworth, Maine. He was in his seventy-fourth year.

Dr. Cabot received his degree from Harvard Medical School in 1898. He was formerly a member of the Mayo Clinic staff and had served as dean of the University of Michigan Medical School. As a practicing surgeon in Boston, Dr.

Cabot won prominence as a specialist in genitourinary surgery. He had been at one time a professor at Harvard Medical School and a chief surgeon at the Massachusetts General Hospital. During World War I, Dr. Cabot served with the Harvard University Unit in General Hospital 22 with the British Expeditionary Force, holding the rank of lieutenant colonel. He was a member of the American Association of Genito-Urinary Surgeons and the American Surgical Association.

His widow and three children survive.

EDSALL — David L. Edsall, M.D., of Cambridge, died August 12. He was in his seventy-seventh year.

Dr. Edsall received his degree from the University of Pennsylvania School of Medicine in 1893. In 1907 he became professor of therapeutics and pharmacology there and from 1910 to 1911 was professor of medicine. In 1912 he was made Jackson Professor of Clinical Medicine at Harvard Medical School. He became dean of the Harvard Medical School in 1918 and held this position until his retirement in 1935. In 1921 he was made dean also of the Harvard School of Public Health, likewise retiring from this post in 1935. During the early years of World War II he was chairman of the Medical Advisory Committee of the American Red Cross. He was a member of the American Academy of Arts and Sciences, the Association of American Physicians, the American Philosophical Society and the National Research Council.

His widow, three sons and six grandchildren survive.

POIRIER — Horace Poirier, M.D., of Salem, died August 14. He was in his sixty-eighth year.

Dr. Poirier received his degree from Laval University, Faculty of Medicine, Quebec, in 1902. He served as chief of obstetrics at Salem Hospital until last fall, when he resigned this position, but continued on the regular medical staff on which he had served since 1927. He was president of the Essex South District Medical Society from 1939 to 1940 and nominating counselor from 1940 to 1941.

His widow, a brother and two sisters survive.

†Four year average

COMMENT

Anterior poliomyelitis cases for July exceeded those for any July since 1935 and represent a number eight times the seven-year median. This does not necessarily mean that a

large outbreak is imminent. The August figure will be a better indicator. Not infrequently the July figure is not a forecast of the year's total.

Mumps showed the highest incidence in July for any year since it was made reportable in 1915.

Bacillary dysentery increased from 1 case in June to 44 in July because of the understandable difficulty of controlling this disease in institutions, especially those handling mentally defective patients, with the present labor shortage.

GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Anterior poliomyelitis was reported from Beverly, 1, Boston, 9, Dedham, 1, Everett, 2, Gloucester, 2, Hardwick, 1, Holyoke, 1, Leominster, 1, Lowell, 1, Marblehead, 2, Marshfield, 1, Medford, 1, Montague, 1, Peabody, 1, Reading, 1, Salem, 4, Somerville, 1, Springfield, 2, Ware, 1, Yarmouth, 1, total, 35.

Diphtheria was reported from Boston, 2, Fairhaven, 1, Haverhill, 1, Lowell, 1, Lynn, 1, Medfield, 1, New Bedford, 2, Newburyport, 1, Quincy, 1, Revere, 1, Springfield, 1, total, 13.

Dysentery, amebic, was reported from Camp Edwards, 1, Regional Hospital, Waltham, 1, total, 2.

Dysentery, bacillary, was reported from Camp Edwards, 1, Waltham (W. E. Fernald School), 20, Worcester (State Hospital), 23, total, 44.

Malaria was reported from Bedford, 1, Boston, 1, Camp Edwards, 53, Cambridge, 1, Cushing General Hospital, 5, Chelsea, 1, Fort Devens, 43, Gloucester, 1, Haverhill, 1, Holyoke, 1, Lawrence, 2, Lynn, 1, Medford, 1, New Bedford, 1, Somerville, 2, Stoughton, 1, Waltham (Regional Hospital), 19, Worcester, 1, total, 136.

Meningitis, meningococcal, was reported from Boston, 5, Easthampton, 1, Fall River, 1, Greenfield, 1, Hull, 1, Medford, 1, Millbury, 1, North Adams, 1, Springfield, 1, Uxbridge, 1, total, 14.

Meningitis, Pfeiffer-bacillus, was reported from Canton, 1, Southbridge, 1, total, 2.

Meningitis, pneumococcal, was reported from Boston, 1, New Bedford, 1, Worcester, 1, total, 3.

Meningitis, other forms, was reported from Medford, 1, Somerville, 1, total, 2.

Salmonella infections were reported from Boston, 1, Falmouth, 1, Malden, 2, Northampton, 2, Salem, 1, Salisbury, 1, total, 8.

Septic sore throat was reported from Boston, 8, Cambridge, 1, Easton, 3, Haverhill, 1, Marion, 1, Merrimac, 2, Quincy, 1, total, 17.

Tetanus was reported from Lowell, 1, Lynn, 1, Plymouth, 1, total, 3.

Trachoma was reported from Salem, 1, total, 1.

Undulant fever was reported from Gloucester, 1, Holyoke, 1, Revere, 1, total, 3.

MISCELLANY

ANNUAL PRIZE SUBSCRIPTION

The annual prize subscription offered by the *New England Journal of Medicine* for the best undergraduate contribution to the *Tufts Medical Journal* has been awarded to Eugene G. LaForet for his paper "Medical Aspects of Submarine Warfare," which appeared in the March, 1945, issue. The paper "Myasthenia Gravis. A complete review" by Albert M. Starr and Bance M. Webber received honorable mention; it appeared in the January, 1945, issue. According to custom, these students will be given a two-year and a one-year subscription to the *Journal*, respectively.

CORRESPONDENCE

PEACETIME CONSCRIPTION

To the Editor: In the August 2 issue of the *Journal* it is stated editorially that "in view of the biologic and psychologic facts that every doctor knows, it is the duty of organized medicine and of each individual physician to throw themselves vigorously into the debate in favor of peacetime conscription." I believe that there are at least three points that merit serious meditation before one comes to any final conclusion in this matter.

Certainly there is little doubt that peacetime conscription would "improve the physical fitness of the Nation's young men" whether or not this is the best method that could be devised seems open to considerable questioning. A sizeable proportion of our physically unfit achieve this status long before they reach draft age. Will military training help these individuals more than preventive measures in infancy and in the schools? Many persons feel that late marriages among our business and professional classes, with their consequently lowered reproductive rate, are partly responsible for weaknesses in our stock. This factor would seem to be aggravated rather than helped by conscription.

Your editorial completely ignores the social and psychologic effects of peacetime military training. This method has been used extensively by many nations in the past in an effort to produce superior physical specimens, but it is questionable if they succeeded in producing superior men in other respects. For while military organizations are unequalled for training and indoctrination, their fame as truly educational institutions is not so striking.

A third point was neglected in your editorial. It was admitted that many intelligent groups were sharply divided in their opinions on this subject. Does it not seem somewhat strange that organized medicine should take such a definite stand on a question that others find debatable, without giving serious and prolonged consideration to factors other than physical fitness?

GEORGE W. COMSTOCK, M.D.

206 High Avenue
Cleveland 15

CAROTID BODY

To the Editor: The July 19 issue of the *Journal* contains an article entitled "Tumor of the Carotid Body" by Dr. Horace K. Sowles. In it he states "Physiologically it [the carotid body] is apparently of no great importance. There is little or no evidence in favor of including it among the glands of internal secretion. The facts that it is sometimes absent and that bilateral extirpation can be carried out without any subsequent symptoms suggest that its function, whatever it may be, is negligible. This being so, the only clinical interest in the carotid body is its pathology."

I should like to point out that Cornelle Heymans received the Nobel Prize in Physiology in 1938 for his investigations on the functions of the carotid body, which started in 1932. Since that time there have been a large number of articles (listed in the *Index Medicus* under the heading "Carotid Body") dealing with the physiologic importance of the carotid body, including a number of review articles in the English literature and one clinical review article (*Am J Med Sc* 208: 681-694, 1944). It is now well known by all physiologists that the carotid (and aortic) bodies are sensory receptors which are stimulated by certain chemical changes in the arterial blood. These receptors respond to low oxygen tension, decreased pH, increased carbon dioxide tension and certain drugs, such as cyanides, nicotine and so forth. When stimulated, these chemoreceptors produce a reflex increase in respiratory rate, depth and minute volume, an increase in sympathetic nervous activity (increase in pulse rate, arterial blood pressure, vasoconstrictor tone and liberation of adrenalin) and an increase in cerebral cortical activity. Although it is true that the chemoreceptors are not essential to life in a normal person, they are of great importance in those clinical emergencies in which the patient suffers from anoxia, since the main defense of the organism against anoxia resides in these chemoreceptors.

BOOK REVIEWS

Immuno-Catalysis By M G Sevag, Ph D With a preface by Stuart Mudd, M D 8°, cloth, 272 pp, with 19 tables Springfield, Illinois Charles C Thomas 1945 \$4 50

That "all proteins — antigens, enzymes, hormones and so forth — are endowed with catalytic activity," is the text of this immunochemical homily. Antigenicity is considered a manifestation of catalytic (enzymatic) activity, the antigen itself corresponds to the enzyme, for which globulin "factors" serve as substrate, with antibodies as the product. The neutralizing actions of antibody on antigen are compared with the effects on enzymes of specific inhibitors structurally related to the substrate, and formed during the course of the reaction. The well documented development of this thesis occupies the first half of the monograph. The second half deals with the behavior of enzymes — in the customary, more restricted sense — as antigens, and describes the corresponding antibodies.

The whole work possesses three distinct values: a reservoir of references dealing with the relation of antigens and antibodies, a synthesis of multiplex data into a hypothesis of engaging simplicity and, finally, a catalyst that will certainly increase the velocity of immunochemical research.

Familial Susceptibility to Tuberculosis Its importance as a public health problem By Ruth R Puffer, Dr P H, Tennessee Department of Public Health 8°, cloth, 106 pp, with 9 figures and 21 tables Cambridge Harvard University Press, 1944 \$2 00

This monograph attempts to translate the factors that turn tuberculous infection into disease. Since the discovery of the causative agent of tuberculosis, scientists, clinicians and public-health workers have delved into the mysteries of resistance. At the present time, the fact is fairly clear, and practically universally accepted, that direct heredity, in the sense that the disease, like syphilis, is transmitted *in utero*, does not exist in tuberculosis. Furthermore, that certain families have a predilection for tuberculosis cannot be explained entirely by household infection. The author reviews quite thoroughly all the work done on this subject, especially that on monozygotic and dizygotic twins, and summarizes the studies on siblings, consorts and offsprings, as well as on the parents of the tuberculous. She concludes that all these studies implicate familial susceptibility as a determinant in the development of tuberculosis. She agrees, of course, that the immediate risk is greatest for susceptible persons who have unusual exposure to tubercle bacilli. Since causation of tuberculosis is a matter both of susceptibility and of exposure, with varying intensity of each, a distinct separation is difficult to obtain. Hence, she pleads for research in the discovery of the factors in the host that determine the resistance or susceptibility to the organism.

Unfortunately, Dr Puffer points only to the well known and tried form of attack against tuberculosis, namely, the search for the disease among contacts especially among members of the family. This principle has applied for the past quarter of a century. Whether or not certain biologic factors exist in certain vulnerable families is still in the realm of conjecture. Undoubtedly social and economic factors of families must also receive consideration. This monograph, however, should serve as a stimulus for further research in the causation of tuberculosis along biologic as well as bacteriologic points of view.

The Marijuana Problem in the City of New York Sociological, medical, psychological and pharmacological studies By the Mayor's Committee on Marijuana 8°, cloth, 220 pp, with 53 tables Lancaster, Pennsylvania Jacques Cattell Press, 1944 \$2 50

The New York Academy of Medicine in 1938, at the request of Mayor LaGuardia, appointed a special committee to study the marijuana problem in the City of New York. The work of the committee was divided into two major divisions:

sociologic and medical. The medical portion was subdivided into clinical, physiologic and pharmacologic.

The sociologic investigation was conducted by trained members of the New York Police Force. They found that the drug was being used extensively in Manhattan, mostly in Harlem, and that the majority of the smokers were Negroes and Latin Americans. They also found that smoking of the drug is not habit-forming in the medical sense of the word and that it does not lead to morphine, heroin or cocaine addiction. The subcommittee on sociology arrived at the conclusion that the drug is not the determining factor in the commission of major crimes, that smoking of the drug is not widespread among school children and that juvenile delinquency is not associated with the use of marijuana.

The clinical study was based on the findings in 72 subjects drawn from penal institutions, determined by a test group of five persons who had had no previous experience with marijuana. The most consistent effect observed was an increase in pulse rate. There was in general an increase in the blood sugar level and in the basal metabolic rate, but in the majority of cases the levels reached did not exceed the high normal limits. An increase in the frequency of urination was often observed, but there was no appreciable increase in the total amount of urine passed during the drug action. Hunger and an increase of appetite, particularly for sweets, were noted in the majority of the subjects, and the taking of candy, sweets and drink inhibited the effects of the drug. Nausea and vomiting occurred in a number of cases. The blood showed no changes, and the circulation rate, vital capacity and tests of kidney and liver function were not different from those of the control period. The positive results observed were not intensified by an increase in dosage, for they occurred in an equal degree after the administration of any of the effective doses used. The alteration in the functions of the organs studied apparently resulted from the effects of the drug on the central nervous system, a direct action on the organs themselves was not observed.

The psychologic tests were carried out on 54 persons — 36 marijuana users and 18 non-users. It was found that the function most severely affected was body steadiness, including hand steadiness. The ataxia is general in all directions, rather than predominate in any particular axis. The effects produced by large doses are systemically greater than those brought about by small ones. The effect of the drug runs a cycle of about eight hours, reaching a peak at the fourth hour. It affects women essentially the same as men, except that the former sometimes reach the peak and the end of the effects more quickly than the latter. The drug taken in pill or in cigarette form has a transitory adverse effect on mental functioning, and the extent of intellectual impairment is related to the amount of drug taken. Indulgence in the drug does not appear to result in mental deterioration. Comprehensive tests were made on the emotional reaction and on the effect on personality, and it was found that changes in basic personality structure did not occur but that some of the superficial aspects of behavior showed alterations. The subject experienced increased feelings of relaxation, disinhibition and self-confidence.

An extensive pharmacologic study was made of crude marijuana preparations and of cannabitol. This study led to the discovery of the active principles, the elucidation of their origin and the assembling of data concerning their chemical structure and biologic activity. The typical effects of marijuana on man are ascribed to actions on the central nervous system.

This monograph should find its place in all medical, public-health and sociologic libraries as a standard reference work on the subject.

Manual of Clinical Mycology By Norman F Conant, Ph D, Donald S Martin, M D, David T Smith, M D, Roger D Baker, M D, and Jasper L Callaway, M D. Prepared under the auspices of the Division of Medical Sciences, National Research Council 12°, cloth 348 pp, with 148 illustrations Philadelphia and London W B Saunders Company, 1944 \$3 50

The study of medical mycology has progressed slowly, due to lack of interest by physicians and in most medical schools, and has been hampered by the confusing mycologic

nomenclature found in most textbooks. Conant and his associates have avoided this error and have presented an understandable classification by simplifying the nomenclature, using only a few well recognized synonyms of the fungi. Instead of the usual introduction discussing cryptogamic botany, about which few physicians are interested, this book starts with the diseases caused by the fungi, a separate chapter covering each disease. Experts in their respective fields contribute a section for each chapter, these include a mycologist, a bacteriologist, a pathologist, an internist and a dermatologist.

Each disease is clearly defined. Its geographic distribution is illustrated by text and picture, the source of infection is noted, and the age, sex and occupation incidences are quoted. The occupational factors of thirteen diseases should be of interest to the industrial physician. The symptomatology is clearly and adequately described. The methods of laboratory examination are so well outlined that even a novice should be able to confirm the clinical diagnosis. The pathologic descriptions are clear cut and readable, the illustrations are numerous and excellent.

The reviewer's only criticism is that 208 pages are devoted to rare diseases, particularly the deep-seated infections, whereas only about 80 pages concern the frequent and widespread dermatomycoses, however, so much has been written about the latter and so little is known about the former that perhaps this is a good fault. In these days of therapeutic interest in the antibiotics, the chapter on contaminants is alone well worth the price of the book. The chapter on the immunology of the dermatomycoses, with its frequent references to trichophyton and oidiomycin, will probably be questioned by some dermatologists. The appendix contains many useful diagnostic and therapeutic formulas.

It is a book that should be in the library of every medical laboratory worker, medical student and clinician.

BOOKS RECEIVED

The receipt of the following books is acknowledged, and this listing must be regarded as a sufficient return for the courtesy of the sender. Books that appear to be of particular interest will be reviewed as space permits. Additional information in regard to all listed books will be gladly furnished on request.

Tropical Medicine. By Sir Leonard Rogers, KCSI, CIE, LL.D., MD, BS, FRCP, FRCS, FRS, and Sir John W. D. Megaw, KCIE, BA, MB, DSc (hon.). Fifth edition, 8°, cloth, 518 pp., with 2 colored plates and 87 text-figures. Baltimore: Williams and Wilkins Company, 1945. \$5.75.

The text of this well known book has been revised in the light of the special needs of military medical officers serving in tropical countries. Many parts have been entirely rewritten, especially the chapters concerning malaria, the dietetic diseases, leprosy, kala-azar, trypanosomiasis and the fevers of the typhus group. The text is well printed with a good type and should serve as a standard reference work on the subject.

My Second Life. By Thomas H. Shastid, MD, LL.B., Sc.D. 8°, cloth, 1174 pp., with 130 illustrations. Ann Arbor, Michigan: George Wahr, 1944. \$10.00.

Dr. Shastid in this second book of his autobiography includes principally material not contained in the first, which was published under the title *Tramping in Failure* in 1937. The doctor writes of his childhood, his youth and his experiences in the practice of medicine in Pike County, Illinois.

The biography is written in a narrative form and is interspersed with a great many stories of local persons and conditions. He tells of his travels abroad and of his interest in medical history, fostered by his professorship at the American Medical College in St. Louis. There is an interesting story of Dr. J. M. Hewitt, in which it is claimed that he made the first roentgenogram in the Western Hemisphere in 1895, when he photographed Dr. Shastid's hand with a borrowed Crookes's tube. The picture of the hand is reproduced, but it is unfortunate that the exact day in 1895 was not recorded. This volume should prove interesting in any biographical collection.

Massage and Remedial Exercises in Medical and Surgical Conditions. By Noël M. Tidy, T.M.M.G., member of the Chartered Society of Massage and Medical Gymnastics and sister-in-charge of the Red Cross Massage Clinic, High Wycombe, England. Sixth edition, 8°, cloth, 480 pp., with 190 illustrations. Baltimore: Williams and Wilkins Company, 1944. \$6.00.

The principal alterations in this edition of a standard work have been made in the sections on fractures, which, in part, have been entirely rewritten to bring them more into line with modern methods of treatment.

Handbook of Industrial Psychology. By Dr. May Smith. 8°, cloth, 304 pp. New York: Philosophical Library, 1944. \$5.00.

This book has been written as an introduction to its subject and does not claim to be a complete treatise. In order, the author discusses fatigue in industry, industrial plant environment, job placement, time-and-motion study, temperaments of workers, especially the nervous type, maladjustment of workers and time lost in industry.

Penicillin in Warfare. A supplement to Vol. XXXII, No. 125 (July, 1944), of the *British Journal of Surgery*. 4°, paper, 115 pp., illustrated. Baltimore: Williams and Wilkins Company, 1944. \$2.50.

In this volume a number of military physicians have collaborated in discussing the use of penicillin as a therapeutic measure in wounds and infections occurring in war areas. Among the subjects discussed are fractures of the femur, gas gangrene, wounds of the chest, head and spine, clostridial infections, gonorrhea and syphilis. An interesting article discusses the prophylactic use of penicillin in the wounds of aerial warfare. A good bibliography completes the volume. This essential reference source should be available to all surgeons.

NOTICES

METROPOLITAN STATE HOSPITAL

The eleventh Postgraduate Seminar in Neurology and Psychiatry will begin Monday, October 1, at the Metropolitan State Hospital, 475 Trapelo Road, Waltham. The program consists of eighty-one two-hour lectures, demonstrations and round-table conferences in anatomy, applied physiology, pathology and roentgenology of the nervous system, clinical neurology, psychopathology and psychiatry.

The lectures will be held every Monday from October 1 to December 10, 1945, and from January 7 to April 22, 1946, in three two-hour sessions from 2:00 to 10:00 p.m. The seminar is open to all graduate physicians. Those interested are requested to register October 1 at 1:30 p.m. at the Metropolitan State Hospital.

THE EFFECT OF CHEMOTHERAPY ON THE DURATION OF THE CARRIER STATE FOLLOWING SCARLET FEVER*

A DANIEL RUBENSTEIN, M.D.,† AND GEORGE E. FOLEY‡

BOSTON

THE utilization of chemoprophylaxis in the control of infections spread by the respiratory tract is a recent development that is gaining ever wider application. In 1939 it was shown that sulfanilamide was effective in preventing streptococcal upper respiratory infections and relapses in rheumatic fever.¹⁻³ Kuhns et al.⁴ found that sulfadiazine, when given prophylactically, diminished meningococcal carrier rates as well as the incidence of meningococcal meningitis. During the course of a scarlet-fever epidemic in a United States naval station, the routine administration of prophylactic doses of sulfadiazine to healthy contacts appeared to be effective in checking its spread.⁵

Conflicting reports have appeared concerning the efficacy of the sulfonamides in preventing complications following upper respiratory infections. Rhoads and Afremow⁶ found that sulfanilamide did not reduce the incidence of sequelae in cases of pharyngitis and tonsillitis. Kernan,⁷ on the contrary, observed that complications were decreased when patients with tonsillitis were treated with this drug. Quite recently it was observed that sulfadiazine in a solution of ethanolamines (Pickrell's solution) administered as a spray to the nose and throat reduced the frequency of bacterial infections following the common cold.⁸ Although Cecil et al.⁹ found that the sulfonamides did not alter the course of the uncomplicated "cold," there was some evidence that in certain cases secondary infections were prevented by the oral use of sulfadiazine. Bacteriologic studies revealed a constant reduction in the total number and variety of pathogens cultured from the upper respiratory tract following the administration of 3 gm. of sulfadiazine daily for four days.

The occurrence of two small outbreaks presented an opportunity to study the effect of chemoprophyl-

axis on the spread of scarlet fever. Although many workers have studied the efficacy of sulfonamides in preventing complications of scarlet fever, little thought has been given to the possibility that treatment of scarlet fever with this group of drugs may reduce the incidence of secondary cases. Among 38 hospitalized cases of scarlet fever, we have observed that 32 patients when discharged from the isolation unit still harbored the identical organism that was present on admission. It is apparent that the problem of late secondary cases is closely linked with the prolonged carrier state that may follow scarlet fever.

PURPOSE AND METHOD OF STUDY

The purpose of this study was therefore to determine whether chemotherapy reduces the duration of the carrier state in the scarlet-fever cases observed in these two epidemics. At the same time, in an attempt to prevent the possible occurrence of secondary cases among the contacts, exposed persons were given small daily doses of a sulfonamide preparation. Unfortunately, the number of contacts in both epidemics was so small that it was impractical to divide them into two groups, one to receive chemotherapy and the other to remain untreated. Nevertheless, interest was centered on the period of communicability of the treated and untreated cases.

Cases that occurred in the first outbreak were treated with sulfamerazine. The duration of the carrier state of these cases was compared with that of cases occurring in the second outbreak, all but 2 of which received no chemotherapy during the acute stage of the disease. Contacts in the first epidemic received small daily doses of sulfamerazine, whereas those in the second were treated with daily applications of Pickrell's solution as a spray.

To evaluate as accurately as possible the immunity status of persons carrying Lancefield Group A streptococci in the nose and throat, the Dick test was performed on all contacts. Serial nose and throat cultures were utilized to determine the duration of the carrier state in cases and contacts.

†District health officer, Massachusetts Department of Public Health.

‡Technical associate in epidemiology, Department of Preventive Medicine and Epidemiology, Harvard Medical School and Harvard School of Public Health.

In addition to the investigation of the outbreaks, further studies on the duration of the convalescent carrier state were made by serial nose and throat cultures of sporadic cases admitted to two contagious hospitals. In one of these institutions, in which chemotherapy was utilized only for severe cases, we observed 13 patients treated with sulfadiazine and 26 untreated cases. The majority of the sulfadiazine-treated patients were from six to twelve years of age and were given 0.5 gm. of the drug every four hours for seven to ten days.

In the second institution where scarlet-fever patients had been treated routinely with sulfathiazole, three groups of cases were studied. One group (12 cases) received no chemotherapy, the second (16 cases) received sulfathiazole, and the third (13 cases) received Pickrell's solution as a spray. Children above the age of six received 0.5 gm. of sulfathiazole five times daily for five to seven days. The Pickrell's solution was administered as a spray to the nose and throat four times daily for twenty-one days. The observation period varied from five to nine weeks.

BACTERIOLOGY

Nose and throat swabs were streaked on 5 per cent horse-blood agar and cultured in beef-heart infusion broth. All mediums contained 0.005 per cent para-aminobenzoic acid¹⁰. Plates were examined after eighteen to twenty-four hours incubation at 37°C and typical beta-hemolytic colonies were fished to beef-heart infusion broth. If hemolytic streptococci were not isolated from the original plate, the broth culture of the swab was appropriately diluted and streaked on blood agar. All Lancefield¹¹ Group A hemolytic streptococci were typed by the slide agglutination method described by Griffith¹². Agglutination of granular or self-agglutinating cultures was facilitated by digestion with trypsin, as described by Allison¹³.

The strains isolated from the 14 cases — 10 of scarlet fever and 4 of sore throat — and 16 contacts in Outbreak A agglutinated with type-specific rabbit antiserum prepared against Griffith's Strain 130 (Type 1). These streptococci grew as glossy colonies. The strains isolated from the 11 cases and 9 contacts in Outbreak B agglutinated with type-specific rabbit antiserum prepared against Griffith's Strain Franklin (Type 5). These streptococci grew as typical matt colonies. Both the Griffith Type 1 and Type 5 strains produced a toxin homologous with that of Strain N Y 5, as determined by toxin-antitoxin neutralization tests in rabbits^{14*}.

EPIDEMIOLOGY

Outbreak A

The first outbreak occurred in a small country orphanage with 31 inmates, 26 of which were chil-

dren four to fifteen years of age. Several of them attended local schools where scarlet fever was prevalent. One of these, a nine-year-old boy, developed scarlet fever late in September, 1943. The original patient made an uneventful recovery, but 10 cases of scarlet fever and 4 of streptococcal sore throat occurred in the orphanage from November 7 to 16. The distribution of cases according to the day of onset is shown in Figure 1. Such a distribution suggests a common source, but this could not be established by the investigation.

Nose and throat cultures of cases and contacts revealed a Group A, Type 1, streptococcus as the

causative agent. This organism was recovered in the first series of cultures from 7 cases and 15 contacts, indicating widespread dissemination of the causative organism among the inmates over a comparatively short interval of time. It is noteworthy that of 15 contacts who harbored the causative organism in the nose or throat, 10, all children, had positive Dick tests (Table 1).

The first cultures were taken after the scarlet-fever cases had received 1 gm. of sulfamerazine daily for five days. When it was discovered that a large proportion of the susceptible subjects (with positive Dick tests) harbored the etiologic agent, it was decided to administer prophylactic doses of a sulfonamide. Half a gram of sulfamerazine was administered once daily to all contacts for ten days. Subsequently, contacts with positive Dick tests were treated for an additional five days. Cultures taken at this time revealed that 6 persons — 3 patients and 3 contacts — still harbored a Type 1 streptococcus. Two of the patients had developed a minor complication — one a cervical adenitis and the other a nasal discharge. These 6 persons were then treated with a 2.5 per cent solution of sulfadiazine (Pickrell's solution) as a spray to the nose

*These toxins were prepared by Dr. Geoffrey Edsall, acting director of the Division of Biologic Laboratories, Massachusetts Department of Public Health.

and throat, administered five times daily for five days. Cultures taken after the spray treatment (twenty-one days after chemoprophylaxis was begun) revealed that Type 1 streptococci had disappeared from the entire group (Table 1). A carrier of Type 1 streptococci was disclosed in the final series of cultures two weeks later. Dick tests performed at that time revealed that a reversal from positive to

the beginning of the study are summarized in Figure 2, which also records the results of Dick tests and nose and throat cultures of the contacts. It was found that 11 healthy persons, including the teacher, carried Type 5 streptococci in the nose or throat. Of 14 contacts with positive Dick tests, 5 harbored the causative organism. Study of air-flow currents* revealed that 20 per

negative had occurred in 1 of the contacts and in 10 of the patients (Table 1).

Outbreak B

The second outbreak occurred among 33 fifth-grade children in a single room of an elementary school with a total population of 495 children distributed among fourteen schoolrooms. Scarlet fever was reported from the involved room only. A total of 9 cases of scarlet fever occurred in this room from December 6, 1943, to January 24, 1944. Two additional cases were revealed during the course of the epidemiologic investigation. The dates of onset (Fig. 1) suggest transmission from patient to patient or from carrier to patient. Nose and throat cultures obtained from all 11 cases revealed a Group A, Type 5, streptococcus as the etiologic agent. The findings in the room at

cent of the air within the schoolroom was being recirculated by means of a unit ventilator. Streptococci were recovered from six of thirty-six blood agar plates that had been exposed for twenty-four hours on desks vacated by children who had developed scarlet fever, and from two cultures taken from dust that had collected on the ventilator fan. Of these eight cultures, two showed Type 5 streptococci. Of twenty blood agar plates exposed in an adjacent room where no scarlet-fever cases had occurred, hemolytic streptococci were recovered from three, none of these were Type 5. When it was discovered that a large proportion of the contacts were carrying a Type 5 streptococcus, chemoprophylaxis was begun in an attempt to protect the susceptibles. All children remaining

*We are indebted to Mr. C. P. Yaglou of the Harvard School of Public Health for the studies of ventilation.

in the room received 2½ per cent sulfadiazine in ethanolamine solution as a spray daily, once during the morning and once during the afternoon. Included in this group were 4 convalescent scarlet-fever cases, all with cultures positive for Type 5

Nose and throat cultures were taken from the family contacts of several of the scarlet-fever patients. Of 23 contacts examined (Fig 3), 13 had cultures positive for Type 5 streptococci. Five secondary cases, in none of which the patients at-

FIGURE 2 Data on an Outbreak of Scarlet Fever among the Children in a Schoolroom

streptococci. After seven days of spray treatment, a second series of cultures revealed that 4 contacts and 3 convalescent patients were still carrying a Type 5 streptococcus. During the second week, spray treatment was restricted to those children who had positive Dick tests in addition to those whose cultures were still positive for Type 5 streptococci. Table 2 indicates the number of carriers before and after spray treatment. It will be seen that after the second week only 1 healthy contact had a positive culture for the etiologic organism.

At the time that the last 4 scarlet-fever patients had been released from isolation and were about to return to school. Of these, 1, who had received chemotherapy early in the course of the illness, had negative cultures. The remaining 3 were still carrying Type 5 streptococci. To eliminate as many potential sources of infection as possible, the convalescent patients with positive cultures were given 1 gm of sulfadiazine daily for four days. At the end of that period and one week later the cultures were negative. Subsequent cultures of the entire group after two weeks and again after four weeks revealed the presence of Type 5 streptococci in the nose and throat of 4 of the convalescent patients. No new infections appeared in the schoolroom.

tended school, occurred among the family contacts of the 11 primary-infection cases. Type 5 strepto-

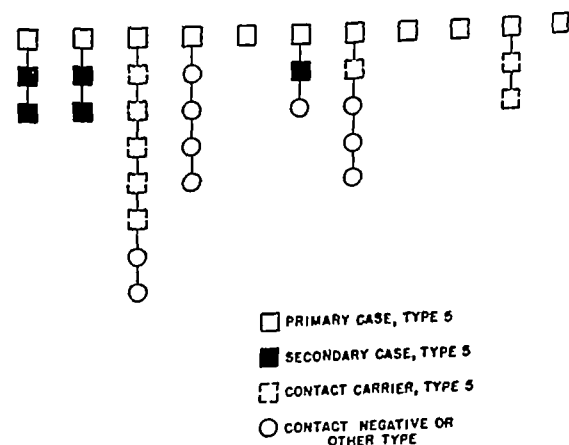

FIGURE 3 Diagram Showing the Spread of Hemolytic Streptococci among Scarlet-Fever Contacts

cocci were recovered from each of these secondary cases.

During the course of this outbreak a total of 25 cases of scarlet fever had occurred in the entire com-

munity Of these, 16 (64 per cent) were associated with the schoolroom outbreak Type 5 streptococci were recovered from a single sporadic case The remaining cases were caused by one of several other serologic types — Types 2, 1 and 6 in order of frequency

for the cases occurring in both epidemics showed striking differences

In Outbreak A the average duration of positive cultures for the sulfadiazine-treated cases was less than two weeks Nose and throat cultures of 6 cases were consistently negative after the third week In 1 case there was a reappearance of the causative organism after cultures had been negative for four weeks

The average duration of the convalescent carrier state in Outbreak B was at least eight weeks One

diazine preparation during their acute illness Following the administration of 1 gm of sulfadiazine daily for four days, in the fifth week after onset cultures promptly became negative for Type 5 streptococci In 3 cases, other types of streptococci not identified with this outbreak replaced the Type 5 streptococcus Here again, subsequent cultures of 1 of these patients disclosed a reappearance of the etiologic organism after a four-week interval during which it had not been demonstrable

Sporadic Cases

Studies of sporadic scarlet-fever cases revealed similar results (Table 3). Nose and throat cultures of 32 (84 per cent) of 38 untreated cases showed at the time of discharge the identical organism that had been present on admission. However, 10 (62 per cent) of 16 sulfathiazole-treated patients had negative cultures after the third week of illness, and 9 (69 per cent) of 13 sulfadiazine-treated ones had negative cultures after the same period of time. Pickrell's solution utilized as a spray in 13 cases produced negative cultures in 10 (77 per cent) at the conclusion of the three-week isolation period.

Although all three chemotherapeutic agents were equally efficacious in reducing the number of patients carrying the causative organism, subsequent cultures revealed that in a considerable proportion there was a reappearance of the initially isolated

eliminate streptococci from the nose and throat of the convalescent carrier.

Experience with several epidemics in schoolrooms suggests that multiple cases of scarlet fever due to a single type of hemolytic streptococcus are by no means infrequent.¹³ Frequently, investigation of contacts during these epidemics reveals the presence of chronic hemolytic-streptococcus carriers, some of whom are found to be either unrecognized cases or convalescent carriers who have returned to school following the expiration of the usual quarantine period.

In the epidemiology of scarlet fever, missed cases and convalescent carriers are far more important as sources of infection than is generally believed. The customary streptococcus-carrier survey does not attempt to differentiate the convalescent case and the healthy carrier. Such surveys will be more useful when an attempt is made to explain the

†Hemolytic streptococci not isolated from 1 case during the period of isolation.

‡Of 3 cases studied.

streptococcus (Table 3). In 5 (50 per cent), of 10 sulfathiazole-treated cases, such a reappearance occurred at intervals ranging from one to five weeks after the cultures had become negative. Similarly, in 5 (55 per cent), of 9 patients who had negative cultures after treatment with sulfadiazine there was a reappearance of the etiologic streptococcus. Only 3 of the patients who had been sprayed with Pickrell's solution were studied after discharge from the isolation hospital. Reappearance of the causative organism was observed in 2 of these.

DISCUSSION

In both outbreaks the etiologic agent appeared to be successfully eliminated from the respiratory tracts of the temporary carriers. Whether the outbreaks were checked by this method is a matter of conjecture. Although a large proportion of the contacts had positive Dick tests, it was impossible to say that these persons were in addition susceptible to the streptococcus itself.

In a study of this type, temporary carriers must be differentiated from convalescent carriers. It was found that although sulfadiazine spray was adequate for the treatment of the healthy carrier, it did not

presence of streptococci in the upper respiratory tract by utilizing all available bacteriologic, clinical and epidemiologic knowledge.

Family studies suggest that children who acquire scarlet fever in school convey the infecting organism into the home, where it is dispersed among the contacts, a proportion of whom may develop scarlet fever or some other streptococcal infection.¹⁶ Also, in family units the carrier rate rises as a result of the introduction of a specific organism into the group by a scarlet-fever patient. Similar observations have been made during the course of institutional outbreaks of streptococcal infection.¹⁶ This factor may account for the high healthy-carrier rates associated with the types of streptococci that are causing scarlet fever in a community.

The frequent occurrence of late secondary cases among family contacts on the return to the home of patients cared for in hospitals is a well known fact. Similarly, in the schoolroom outbreak it was shown that with one exception each of the untreated patients who had returned to school still harbored the incriminated streptococcus in the nose and throat at the expiration of the three-week quarantine period.

Our observations suggest that the administration of sulfathiazole or sulfadiazine to scarlet-fever patients results in the development of a temporary period of so-called "cultural latency," during which the causative organism cannot be isolated from the mucous membranes of the nose and throat. After an interval of one to five weeks, however, there is a reappearance in the cultures of the streptococcus that had been isolated earlier in the course of the infection. In seeking an explanation for the observed period of "cultural latency," it may be pointed out that the fundamental mode of action of the sulfonamides appears to be bacteriostatic rather than bacteriocidal.¹⁷

The question arises whether this period of latency has any effect on the incidence of late secondary cases. Some data concerning this point were available at the contagious hospital where the sulfathiazole-treated cases had been studied. At this hospital 455 cases of scarlet fever had been treated routinely with sulfathiazole over a period of two years — 1942 and 1943. Examination of the hospital and board-of-health records revealed that following discharge of the primary cases from the isolation unit, 25 secondary cases — an incidence of 5.4 per cent — had occurred among the family contacts. From 1939 to 1941, inclusive, following the discharge of 398 hospitalized patients who had received no chemotherapy, 28 secondary cases — an incidence of 7 per cent — were reported among the family contacts.

The interval between the time of discharge of the primary case and the occurrence of the first case of secondary infection was established for each of the two groups. The average interval was 9.2 days for the treated cases and 12.6 days for the untreated ones. From the standpoint of the incidence of secondary cases and of the interval between the discharge of the primary case and the occurrence of the first secondary infection, there was no significant statistical difference between the two groups.*

These observations indicate that the period of "cultural latency" has little effect on the spread of scarlet fever. Additional studies have been undertaken to ascertain the effect of chemotherapy on a larger number of cases. The results of study of untreated cases emphasize the arbitrary nature of the isolation period in scarlet fever. Since the great majority of patients harbor the etiologic organism at the time of discharge from the isolation hospital, it is apparent that the customary three-week isolation period does not accomplish its purpose.

Although it has been demonstrated that the sulfonamides are of therapeutic value, there is little or no evidence that the routine use of chemotherapy has any effect on the incidence of late secondary cases. In this connection, the problems of drug sensitivity and drug fastness merit careful consideration. It

must be borne in mind that the sulfadiazine drugs have been most effective in the treatment of the fatal complications of scarlet fever. It would be unfortunate if their value for these secondary infections were impaired by the development of drug-resistant strains. From the point of view of controlling the spread of scarlet fever, there appears to be little justification for the routine treatment of patients with the sulfonamides.

SUMMARY

The epidemiologic investigation of two small outbreaks of scarlet fever, one occurring in an orphanage and due to a Type 1 streptococcus, and the other occurring in a schoolroom and due to a Type 5 streptococcus, presented an opportunity to study the effect of chemotherapy on temporary and convalescent carriers.

In both epidemics the utilization of small daily doses of a sulfonamide preparation — sulfamerazine in the first instance and sulfadiazine (Pickrell's solution) in the other — apparently reduced to a minimum the number of persons carrying the incriminated organism.

Studies among the families of children who acquired scarlet fever in the schoolroom outbreak revealed a spread of the causative organism to a large proportion of the family contacts, with the occurrence of several secondary cases.

A study of a group of untreated scarlet-fever patients showed that when discharged from isolation hospitals the majority carried the same type of streptococcus that was present on admission.

A large proportion of scarlet-fever cases treated with certain of the sulfonamides developed a temporary period of "cultural latency." In approximately half these cases, however, the original streptococcus reappeared in the cultures after an interval of one to five weeks.

A study of sulfathiazole-treated cases suggests that the period of "cultural latency" has no effect on the incidence of late secondary cases.

HODGKIN'S DISEASE*

Report of a Case of the Mediastinal Type with Leukopenia and Terminal Atelectasis

SOL LEVY, M D †

SPRINGFIELD, MASSACHUSETTS

SINCE Hodgkin's¹ original description in 1832 of the disease known by his name, many papers have appeared in the medical literature that attempt to clarify both the etiology and pathology as well as the symptomatology of this illness.

So far as the etiology is concerned, the cause of the disease still remains unknown, although two main theories have been put forward to explain its origin.² The first holds that the changes in the lymphoid tissues are the result of an infection, the disease thus being a specific infective granuloma of unknown origin. The second theory, on the other hand, considers the alterations in the lymph nodes as neoplastic, thus placing the disease in the category of true neoplasms. The pleomorphism of the microscopic picture, consisting of necrosis with subsequent fibrosis, suggests an inflammatory lesion, whereas the local spread and the uniformly fatal outcome of the disease are characteristic of malignancy. The theory that Hodgkin's disease represents a special form of tuberculosis has been almost entirely disregarded.

Several pathological classifications have appeared, the most recent one, by Jackson and Parker,³ dividing the disease into three types: paraganuloma, granuloma and sarcoma. This division was made on the basis of two features, namely the presence in each of the so-called "Reed-Sternberg" cells and the transformation, in the course of time, of one type of the disease into another. According to these authors, Hodgkin's paraganuloma bears little or no resemblance to a true tumor, either in its histologic picture or its clinical course, but because of the complete lack of invasiveness, the lymphocytic infiltration, the often scattered, isolated Reed-Sternberg cells and the comparatively benign course, it is considered an infectious process. The same holds true for Hodgkin's granuloma, in which, according to these authors, the frequently scattered, isolated Reed-Sternberg cells, viewed

from the pathological standpoint, and the irregular bouts of fever, the marked anemia in absence of bleeding or widespread invasion of the marrow, the polymorphonuclear leukocytosis and the prominent and persistent tachycardia from the clinical point of view are more characteristic of an infectious process than of a tumor. Hodgkin's sarcoma, however, is considered by Jackson and Parker as a true neoplasm. This opinion is based on the uniformity of the cellular constituents, the aggressive, invasive nature of the process, the extremely short duration of life and the not infrequent finding of a large destructive tumor with comparatively few metastases.

So far as the symptomatology is concerned, great difficulties were encountered in dividing the disease into different types, because of the wide scope of the illness and its numerous diverse, protean symptoms. Most authors still accept Ziegler's⁴ plan, which divided the disease clinically into nine forms — acute, localized, general, mediastinal, larval or abdominal, splenomegalic, osteoperiostitic, atypical (gastrointestinal — Mikulicz's disease) and mycosis fungoides. It is beyond the scope of this paper to discuss all these forms, but it should be noted that, in spite of Ziegler's classification, there is often a clinical transformation from one of these types into another.

The following case is reported because of its unusual combination of clinical symptoms and the diagnostic difficulties it presented.

C. G., a 28-year-old man, was admitted with the chief complaint of severe vomiting of 2 weeks' duration. Two weeks prior to admission the patient started to vomit 2 hours after taking food and also experienced considerable midepigastric pain. There was also marked weight loss during this period. When admitted to the hospital he presented symptoms of partial intestinal obstruction and marked dehydration.

The past history revealed that the patient had been treated for peptic ulcers for the last 5 years. This type of treatment was undertaken on the basis of the clinical symptoms, which were fairly typical of a peptic ulcer, although repeated gastrointestinal x-ray studies failed to show any evidence of ulcer.

*From the Medical Service of the Wesson Memorial Hospital.
†Formerly, intern, Wesson Memorial Hospital.

The regime consisted of a moderate Sippy diet with the addition of alkali, antispasmodics and sedatives. The patient carried out this regime fairly conscientiously, and up until the beginning of the present illness showed no acute symptoms related to the gastrointestinal tract. A complete chest examination, including x-ray films, which was done 1 year before admission, was entirely negative. Six months prior to admission he was hospitalized for 2 weeks for a sprain in the lumbar spine, from which he made a complete and uneventful recovery. Otherwise the past history was uneventful.

The patient's father died of a leukemic condition, the exact nature of which could not be determined. The patient was married and had five children, all of whom were in good health. He had been working as a dispatcher in a war plant for over five years and had never been exposed to any chemicals, such as benzol.

Physical examination on admission showed a markedly dehydrated, poorly nourished man, presenting a clinical picture of partial intestinal obstruction. There was evidence of recent weight loss. Except for some tenderness in the right upper quadrant of the abdomen, the examination was negative. No masses were felt, and there was no enlargement of the liver or spleen, nor were there any palpable lymph nodes.

The urine was negative and had a specific gravity of 1.014. The red-cell count was 3,960,000 and the hemoglobin 65 per cent. The white-cell count was 3100, with 51 per cent polymorphonuclear leukocytes, 47 per cent lymphocytes and 2 per cent eosinophils. A slight polychromasia with anisocytosis was noted. A blood Hinton test was negative. The sedimentation rate was 23 mm in 1 hr (Wintrobe method). A blood culture was negative. The icteric index was 5.

A second blood examination, made 10 days after admission, revealed the red-cell count and the hemoglobin to be about the same as on admission, but the white-cell count had increased to 4700. The differential count was approximately the same as on admission. The reticulocyte count was 1.8 per cent, and the blood platelets numbered 350,000. A blood culture was again negative, and the sedimentation rate had decreased to 12 mm in 1 hr. A gastric analysis showed a faint trace of combined hydrochloric acid but no free hydrochloric acid in the fasting specimen. After histamine injection a faint trace of free hydrochloric acid appeared, but not enough for exact values to be ascertained. Daily stool examinations for occult blood revealed positive findings on four occasions and negative values on one. Agglutination tests for typhoid, paratyphoid and undulant fever were negative. The total serum protein was 7.2 gm per 100 cc, the albumin fraction being 4.5 gm, and the globulin fraction 2.7 gm. The urine was negative for Bence-Jones proteins.

One month after admission the white-cell count began to show abnormal values in the form of a definite leukopenia, ranging between 975 and 1700 cells, as determined by daily examinations. The differential count showed a neutrophilia, with lymphocytosis on several occasions, but at no time an eosinophilia. On two smears a large number of metamyelocytes and a few myelocytes were found, in addition to many degenerating white cells and basophilic stippling of the red cells. There were also moderate hypochromia, anisocytosis and polychromasia. Except for these two occasions, however, the differential count showed normal values relatively, in spite of the marked leukopenia. The red-cell count during this period varied between 3,000,000 and 3,500,000, and the hemoglobin between 55 and 65 per cent. The reticulocyte count varied between 3.8 and 9.4 per cent, probably as a response to liver therapy. The sedimentation rate ranged between 12 and 20 mm in 1 hour and the total protein values remained the same — 7.2 gm per 100 cc. The gastric analysis was repeated and again showed no free hydrochloric acid on the fasting specimen, but a slight trace appeared after histamine injection. The icteric index was again 5. A blood culture was negative for the third time. A sternal-marrow puncture on two occasions showed entirely normal smears, but microscopic examination of the bony tissue of the marrow showed definite atrophy and fibrosis. Repeated urinalyses were negative except for slight traces of albumin and bacteria in the sediment. Sputum examination was negative.

About 1 week before the patient's death, the white-cell count increased slightly, but steadily, finally reaching values

between 2500 and 3000, but the differential count remained the same. At the same time, the red-cell count dropped sharply until it reached 1,100,000. The hemoglobin also decreased gradually to 50 per cent. The platelet count, however, remained the same, as did all the other laboratory findings.

An electrocardiogram was negative, except for evidence of slight myocardial damage.

Two complete gastrointestinal series, including a barium enema, were performed 3 months apart, and both were negative. A gall-bladder series (Graham-Cole test) was negative. A flat plate of the abdomen and an intravenous pyelogram were negative. Complete x-ray examination of the long bones, skull, sternum and spine revealed entirely normal findings. Several chest x-ray films were taken, and up to 2 weeks of death were negative, at that time the chest plate for the first time showed complete consolidation of the right base involving the middle and lower lobes. A diagnosis of lobar pneumonia was reported by the roentgenologist. An x-ray film of the chest taken 5 days later showed complete consolidation of the entire right lung. The left lung was clear, and the heart was not displaced. A diagnosis of pneumonia and pleurisy with effusion was made. Another chest film taken 5 days later showed complete opacity of the right side, with no displacement of the heart. A slight increase of lung markings on the left was also reported.

On admission the patient presented the clinical picture of partial intestinal obstruction. He was unable to retain food and complained of severe cramplike pain in the midepigastric region. Following the subsidence of the obstruction he was able to retain a soft diet, but the midepigastric pain continued to be present 1 to 1½ hours after food intake. He also lost weight gradually. There was no fever.

Physical examination 3 weeks after admission revealed marked tenderness and rigidity in the right upper quadrant of the abdomen, the liver was palpable 2 fingerbreadths below the right costal margin. No lymphadenopathy, splenomegaly or tenderness over the splenic region was found, but there was some tenderness on palpation over the flat bones, especially over the sternum. The prostate was not enlarged, tender or nodular. Neurologic examination showed hypoaffective tendon reflexes and normal superficial reflexes. There were no sensory disturbances, and the vibration sense was normal.

The patient's condition remained practically unchanged during the 1st month of hospital stay, but he then began to lose ground, slowly but steadily. He started to run a low-grade remittent type of fever, which persisted for 3 weeks, when the temperature finally rose to 104°F and became sharply intermittent. He complained of severe headaches and again started to vomit. He became extremely weak and the tenderness over the flat bones, especially over the sternum, continued to increase in severity. On one occasion the spleen appeared to be palpable on deep inspiration and there was marked tenderness over the splenic region, which persisted until death. At no time, however, were there any palpable lymph nodes. The patient's general condition rapidly deteriorated and he lost markedly in strength and weight.

Two weeks prior to death, the patient suddenly developed an increasingly severe cough, productive of a small quantity of white mucus, associated with this was bilateral wheezing, especially marked over the right side of the chest. In spite of the x-ray report of lobar pneumonia, a clinical diagnosis of obstruction of the right lower main bronchus producing atelectasis of the right lower and middle lobes was made. Three days later there was a complete absence of breath sounds over the right lung with some expiratory wheezing rales on the left side. Clinically there was slight dyspnea and cyanosis, and the cough decreased in severity. This condition continued for 1 week, when the dyspnea markedly increased and the patient began to expectorate large amounts of thick, greenish mucus. Chest examination revealed many expiratory wheezing rales in both lungs and moist bubbling rales at both bases. He then developed for the first time signs of mediastinal pressure — severe difficulties in swallowing and hoarseness. He died 48 hours later.

Treatment consisted in the beginning of supportive measures such as glucose, saline and amino acid infusions, alkali and antispasmodics. As soon as he was able to retain food, he was given small frequent feedings. After the diagnosis of hypochlorhydria was established, he received dilute hydrochloric acid before meals. The diet was high in carbohydrates and proteins and rich in vitamins. The hypochromic anemia

in the beginning of the illness was combated with iron and crude liver extract. Because of the intermittent type of temperature, the patient was given a course of penicillin, receiving a total of 1,000,000 units intramuscularly in a period of 10 days. This, however, had no effect on the fever. He also received a course of Pentnucleotide (10 cc intramuscularly three times a day for sixteen injections) because of the leukopenia and neutrophilia. This, too, was entirely unsuccessful. He also received eleven 500-cc blood transfusions over a period of 2 months. Otherwise the treatment was purely symptomatic and supportive.

Autopsy

At autopsy the right pleural cavity contained 2500 cc of straw-colored fluid. The right lung was entirely collapsed, and the left lung, as well as the heart, was markedly displaced to the right. At the root of the right main bronchus there was a large tumor mass, measuring 6 by 4 by 2.5 cm. There were also six peribronchial lymph nodes, of pea to bean size, around the root of the right main bronchus. The liver was markedly enlarged, weighing 2020 gm, but the cut surface was normal. The spleen was somewhat enlarged, weighing 280 gm, but showed a normal cut surface. No enlarged abdominal or superficial lymph nodes were found. The sternal marrow appeared to be paler than usual. Microscopical examination of the lymph nodes showed many typical Reed-Sternberg giant cells, and the sternal marrow again was atrophic and fibrotic. The liver showed a mild degree of amyloidosis. The spleen appeared to be normal. **Diagnosis: Hodgkin's disease.**

DISCUSSION

The data derived from the history of this case, as well as the physical findings and the clinical course of the disease, permitted the diagnosis of Hodgkin's disease, which was later confirmed by autopsy findings. Not until two weeks prior to the patient's death, however, did the clinical picture become clear enough to permit a definite diagnosis of this disorder. Up to that time there were many findings suggesting Hodgkin's disease without being pathognomonic of this disorder. A brief review of the clinical course will demonstrate the diagnostic difficulties in this case.

The prodromal symptoms were related to the gastrointestinal tract. In spite of repeatedly negative x-ray findings, the clinical symptoms were so typical of a duodenal ulcer that the patient's physician felt justified in putting him on an ulcer regime. The fact that Hodgkin's disease may be preceded by gastrointestinal disorders was stressed both by Rolleston⁵ and by Bramwell⁶ as early as in 1909. In this case the gastrointestinal disorders finally became severe enough to produce a picture of partial intestinal obstruction, for which the patient was originally referred to the hospital. During the first weeks of his hospital stay, the clinical picture was characterized by generalized weakness and loss of weight, so that at one time a diagnosis of pulmonary tuberculosis was considered. This was ruled out, however, by repeated chest x-ray and laboratory examinations.

Although from the etiologic point of view tuberculosis is still favored by some investigators, there is general agreement that, clinically, tuberculosis follows rather than precedes Hodgkin's disease. This position was further strengthened by Ziegler's⁴ investigations, showing that in 25 per cent of patients

with Hodgkin's disease the terminal picture was that of miliary tuberculosis. According to Jackson and Parker,³ generalized weakness and loss of weight, for which no cause can be found, are not infrequently the first symptoms and may be most difficult ones to evaluate. The fact that Hodgkin's disease in its initial stage may be marked by the most diverse symptoms and signs was also stressed by Jackson and Parker.

To the prodromal symptoms of gastrointestinal disorders, generalized weakness and loss of weight might be added in this case the hypochlorhydria of the gastric juice and the mild hypochromic anemia, findings that, according to Ewing,⁷ are not infrequently noted and may dominate the clinical picture for some time. Fever occurred fairly late in this case. At first it was of the remittent type, without, however, ever resembling the typical Pel-Ebstein fever. Later it became sharply intermittent, suggesting a more or less septic condition. Repeated blood cultures, however, were negative, and a course of penicillin produced no changes.

The blood picture was both bizarre and puzzling. At first there was a mild to moderate hypochromic anemia, which at times showed a tendency toward the pernicious type, but which responded fairly well to liver and iron therapy, as evidenced by the gradual increase in reticulocytes. Whereas the red-cell picture appeared to be reasonably stable, the white-cell count showed a marked leukopenia which continually increased in severity. On several occasions a neutrophilia was also present, which, however, resisted treatment with Pentnucleotide. On two occasions young white cells were also found, but they were not persistent and on subsequent smears were absent. The blood platelets were normal. At no time was there an increase in eosinophilic cells, which some authors, among them Bunting,⁸ describe as one of the most significant diagnostic signs in Hodgkin's disease. One week prior to death there was a slight but steady increase in the white cells, whereas the red-cell count dropped markedly. Repeated blood transfusions were ineffective. A smear of the sternal marrow, which is also considered to be a helpful diagnostic procedure, appeared normal and did not clarify the clinical picture.

Other diagnostic procedures, such as complete gall-bladder and kidney studies, as well as x-ray examination of the long and flat bones, agglutination tests and numerous blood chemical tests, revealed normal values.

The physical signs were extremely vague. Except for a progressing hepatomegaly, the findings were practically nil until two weeks prior to death. There was no palpable splenomegaly, except for one occasion when the spleen seemed to be palpable on deep inspiration. Superficial lymphadenopathy was absent during the entire course. The tenderness over the flat bones, especial

sternum, and over the splenic region, should, however, be mentioned. Although hepatomegaly is mentioned by many authors as a fairly consistent finding in Hodgkin's disease, the occurrence of splenomegaly and superficial lymphadenopathies appears to be a much more frequent finding both in Hodgkin's granuloma and in Hodgkin's sarcoma and seems to be fairly pathognomonic of these two types, even the mediastinal form (Jackson and Parker,³ Ewing,⁷ Boyd,² Cecil⁹ and others)

A striking change in the clinical picture appeared two weeks before death. Then for the first time, mediastinal-pressure symptoms occurred, such as atelectasis of the right lung due to compression of the right main bronchus, difficulties in swallowing and hoarseness. This picture appeared to be fairly consistent with that described by other authors as typical of the mediastinal type of Hodgkin's disease. Up to that time, as already mentioned, the clinical picture was characterized by vague protean findings, some of which were suggestive but not pathognomonic of this disorder.

SUMMARY

A case of Hodgkin's disease, mediastinal in type and characterized by an unusual combination of prodromal symptoms and signs, is described, and the clinical course and the laboratory and autopsy findings are discussed.

MEDICAL PROGRESS

PHYSIOLOGY

HEBBEL E. HOFF, M.D.*

MONTREAL, CANADA

THE re-examination of established principles often proves to be as effective a means of progress as the exploration of new fields. This is especially likely to occur in those instances where the weight of long tradition or great authority and the superficial appearance of reasonableness have combined to discourage the critical analysis of a doctrine. The demand for re-evaluation within recent years of two well buttressed concepts may therefore be viewed as important indications of progress in physiology and medicine. In both, which are discussed in the first two sections below, revision of basic physiologic tenets is involved, along with reconsideration of means of treatment. The first instance concerns the physiologic processes that participate in the production of edema in congestive heart failure, which have required renewed study in the light of revised methods of treatment. The second has to do with clinical observations on the abuses of recumbency and bed rest, which point to the need for more adequate data on the physiologic changes that occur in these circumstances, particularly in the aged and obese.

EDEMA IN CONGESTIVE HEART FAILURE

The subject of edema in congestive heart failure has been reopened through the examination of the value of restriction of fluid and salt in studies in which the two factors were varied separately.

Schroeder¹ studied 23 patients with congestive heart failure in whom restriction of salt intake to approximately 10 gm daily was sufficient to establish diuresis. When, in these circumstances, water intake was increased, edema was not increased. Occasionally, diuresis increased when added water was taken, and diminished with restriction of fluids. Schroeder concluded that restriction of salt is an important feature of the regime in congestive heart failure, whereas restriction of water is not essential.

Similar conclusions were reached by Proger, Ginsberg, and Magendantz,² who gave 4 patients recovering from congestive heart failure 10 to 12 gm of salt daily in addition to a dietary intake of 5 to 7 gm. Within four to eight days these patients developed a clinical picture indistinguishable from congestive heart failure, which was remedied by digitalis. Three

*Joseph Morley Drake Professor of Physiology McGill University

patients were permitted to increase their fluid intake to 3000 cc daily without increase in salt intake. In none of these were there any noticeable harmful effects.

Finally, Schemm^{3,4} has shown that water has valuable diuretic properties, and that when water in excess of daily requirements is given, especially when sodium is moderately restricted and an acid-ash diet consumed along with moderate amounts of dilute hydrochloric acid or ammonium chloride, edema and other fluid accumulations disappear and the symptoms of congestive failure are relieved. Edema of other origins appears also to be favorably influenced. Fluid intakes as high as 5000 to 8000 cc a day have been employed successfully in such treatments. Presumably a high water intake is effective because it provokes an active diuresis, even in badly damaged kidneys, in the course of which excess salt is lost even though the urine is extremely dilute. Reduction in the salt content of the body fluids results in further loss of water to maintain osmotic equilibrium, with the net result that fluid is lost in greater volume than the ingested water.

These studies, which call attention to the role of salt and water accumulation as an important factor in the edema formation in congestive heart failure, also suggest that such accumulations may in fact precipitate the attack of failure. This is confirmed by the recent studies of Warren and Stead,⁵ who found that resumption of a normal salt intake and an additional 12 gm salt daily by two patients who had recovered from failure on a low-salt and diuretic regime led to typical attacks of congestive heart failure. The plasma volume increased prior to the onset of failure, but the venous pressure did not rise beyond the control range. The authors are therefore inclined to view the increased retention of salt and water, followed by an increased plasma volume, as the primary events in the collection of edema, and to discard the conventional theory that the accumulation of fluid results from increased venous pressure, or tissue anoxia, in heart failure.

Evidence that tissue anoxia cannot be responsible for edema formation is presented in another report by the same authors,⁶ in which it is shown that the protein content of edema fluid is not abnormally increased, nor is fluid obtained in patients with frank tissue anoxia, whereas the protein content of fluid collected after prolonged elevation of venous pressure is markedly elevated. The accumulation of salt and water is credited, instead, to a deficient renal excretion. This in turn may be due to excessive production of adrenal cortical hormones or to altered renal circulatory dynamics. The latter appears to be the most reasonable. The following sequence of events is then presumed to occur: failure of cardiac output, failure of renal circulation and consequent failure of salt excretion, water retention, increase in capillary pressure as the result of the augmented plasma volume, and consequently, in-

crease in extracellular fluid or edema. The increased venous pressure is thus viewed as the *result* of retention of salt and water — not the *cause* of it.

From an *a priori* standpoint this account fails to be completely satisfactory, depending as it does on the establishment of conclusive evidence that plasma volume does in fact increase before venous pressure is raised. It is difficult to accept the suggestion that the heart fails enough to derange the circulation in the kidneys before the venous pressure rises. It is generally assumed that the first reaction of the failing heart is to maintain a normal output through the operation of Starling's law of the heart, whereby the residuum of blood left in the ventricle by an incompletely effective systole is added to the normal diastolic inflow to distend the heart and thus to increase stroke volume to the point where a normal output is maintained at the expense of a slight increase in venous pressure. Failure begins when this mechanism is no longer successful, and increased filling is followed by diminished output. Thus, adding to blood volume in a heart at the point of failure precipitates failure, whereas reducing the volume, as by venesection or pooling of blood behind tourniquets, actually improves cardiac output by reducing the diastolic overload.

PHYSIOLOGY OF REST

Under the stress of an increasing demand for hospital and nursing care, one of the most firmly established of all therapeutic principles is being subjected to critical scrutiny. In the light of this re-examination, the doctrine of rest as a curative measure is seen to have certain important limitations, a number of which are brought out in a recent symposium⁷⁻¹¹ and in subsequent reports.¹²⁻¹⁴ The discussion is opened by Harrison, who recalls that John Hunter lived possibly twenty and certainly eight active and productive years after the first symptoms of coronary arterial disease, whereas James Mackenzie survived his initial cardiac attack by seventeen years, during fifteen of which he continued to play golf. He then reviews experiment carried out with Thomas,¹⁵ in which the survival rate was studied in rats after damage was inflicted on the myocardium by burning the left ventricle. In rats whose activity was restricted to approximately 10 per cent of that of unrestricted controls only 7 survived out of 49, whereas 21 out of 41 survived in the control group. Unconfined rats resumed normal activity in five days, as shown by their optional use of a treadmill in the cage. Forced, strenuous exercise (swimming) failed to influence mortality if it were not begun before forty-eight hours after the cardiac trauma. From these experiments the authors concluded that physical activity within the range of tolerance may be more beneficial than complete rest. They call attention, however, to the obvious fact that restraint, even though it may reduce skeletal muscular activity,

can hardly be termed rest, and it is highly uncertain that the cardiovascular load under these circumstances is in any measure diminished. This may be comparable to the patient who is forced by the physician to maintain an "unhappy recumbency" instead of a "happy sitting." Harrison lists the following as advantages to be sought in prolonged bed rest: a decreased liability to rupture of the heart, a better circulation to the brain during the period of circulatory collapse, and a firmer and smaller scar. The following are cited as disadvantages: the tendency to the formation of pulmonary edema, a diminished circulatory velocity, with a consequent tendency to intravascular clotting, and the development of hypostatic pneumonia, particularly in elderly people.

Levine cites as advantages of bed rest a diminished metabolism, a slower heart rate and a lower blood pressure, all of which diminish the work of the heart or improve its efficiency. On the contrary, the improved venous return associated with recumbency increases the cardiac output by some 25 per cent and tends to counterbalance the gains noted above. It is recognized that attacks of cardiac asthma are more frequent at night after several hours of recumbency, and their victims often learn to overcome them by sitting at the edge of the bed with the feet dependent. By this process, the fluid in the lungs is diminished and the venous blood is pooled in the dependent limbs, thus relieving the overdistended heart and permitting it to contract more efficiently. Even when the patient cannot sit up, it may be possible to carry out both active and passive limb exercises, and to elevate the head of the bed to begin to condition the cardiovascular system for the ultimate resumption of the upright position.

There appears to be general agreement that after surgical operations, particularly those involving the pelvis and abdomen, venous return from the limbs is delayed and serves as the basis for embolus formation in the small veins and venules of the dependent portions of the limbs, particularly in the obese and aged.¹⁶⁻¹⁹ Elevation of the limbs and exercise, especially the latter, markedly decrease the foot-to-carotid-sinus circulation time.^{16, 17} Walking soon after operation has been advocated as a measure to minimize postoperative thrombosis. Other advantages of early walking after surgery have been suggested as follows: improved gastrointestinal function, with lessened incidence of abdominal distention, improved muscular strength and absence of asthenia, which lead to a more rapid resumption of full activity, more rapid healing of the wound, improvement in morale, and economy in hospital beds and nursing care and in the cost of illness to the patient.

Dock emphasizes that bed rest is far from physiologic, involving long periods in the dorsal recumbent posture, usually with sedation to suppress the normal tendency to change frequently, and diminished

vital capacity and tidal volume. Unless specifically warned against it, the patient will many times a day repeat the Valsalva experiment (taking a deep breath, closing the glottis and contracting the expiratory muscles), when on the bedpan, expelling flatus or moving upward in bed. This maneuver places a great strain on the cardiovascular system, and often causes sudden death after myocardial infarction.

The symposium closes with a discussion of the psychosomatic aspects of rest, calling attention to the fact that the symptom of fatigue is only in rare cases at all related to exhaustion of muscular energy, but rather stems from an inability to direct energy output into properly balanced creative and destructive outlets. Therapy must therefore aim to utilize rather than to blockade the available energy of the patient.¹¹

It is obvious that these objections are directed not so much at the doctrine of rest itself as against abuses and misconceptions of the principle. Enforced muscular inactivity does not constitute rest, and may in fact prevent rest. Mental rest is often achieved by a combination of physical activity in a proper environment. Various operations of orthopedic surgery may effectively place a fractured bone at rest without at the same time depressing the functions of nearby joints and muscles. The complete bed rest of the patient with tuberculosis is accompanied by conscious or unconscious psychotherapy aimed at allaying anxiety and arousing a desire to carry out the treatment in every detail.¹⁴ Rest must therefore be prescribed, like any other therapeutic measure, with a clear idea of the aims sought by its employment and of its harmfulness when employed excessively and inappropriately. "Whenever we put a patient to bed," advises an editorial in the *British Medical Journal*,²⁰ "we should ask ourselves what we hope to achieve, and it must be something more than a tidy ward, a convenience for examination or a substitute for a convalescent room."

Closely associated is the problem of limitation of exercise in chronic illnesses, such as rheumatic fever, in which the decision may lie between a life of semi-invalidism and a virtually normal existence. Here the report of Kohn and McEldowney²¹ may serve as a guide to the extent to which persons with seriously impaired hearts may lead normal lives. The study concerns the fate of 233 former pupils of a special school for children who, because of disease, accident or congenital deformity, could not attend a regular school with "safety and profit." Eighty-five per cent had rheumatic heart disease, and 9.4 per cent suffered from congenital lesions of the heart. Twenty-five per cent had died, and 20 per cent had had recurrences of rheumatic fever. Of 130 pupils re-examined between the ages of seventeen and thirty-three years, only 5 per cent had never worked or were not working at the time of re-examination. Thirty-two women had married, and

of these, 14 had had one child, 3 had had two, and 2 had had four, in no case had the heart lesion affected adversely the pregnancy or labor. Fifty per cent of the women were doing their own housework, and many were performing heavy work.

It is obvious that, despite the seriousness of their heart disease, a majority of the persons included in the study had been able to enjoy, within their limitations, active and productive lives. Whether the mortality within the group would have been any less had their activity been more rigorously curtailed is open to question, but it is probable that the mortality in this group of patients was an indication of the seriousness of the heart disease, and might well have been as great if they had been receiving sanatorium care as semi-invalids during the whole period of the study.

(To be concluded)

CASE 31371

PRESENTATION OF CASE

A fifty-year-old widowed chauffeur was admitted to the hospital because of progressive anorexia, weakness, malaise and weight loss.

Sixteen years before admission the patient had had an acutely inflamed gall bladder drained. Seventeen days postoperatively he was discharged with a small draining sinus, which had continued to drain creamy yellow to green purulent material up to the time of admission. The drainage was intermittent, with frequent periods of several days during which the sinus tract closed. Within a few days there invariably followed a short period of local discomfort

and often pain, which was followed by reopening of the sinus and profuse drainage for a few days. Approximately one year after the operation, while doing heavy work, an orange-sized hernial mass suddenly appeared at the site of the operative scar. This hernia had never been painful and had not increased in size. Five years before admission he had had "pneumonia," which was treated at home. The patient had otherwise been entirely well until about two years before entry, when he began to feel sluggish, had no energy and lost ambition and interest in his work. He began to lose his appetite and weight. One year before admission he began to have mild attacks of "asthma," which became worse, two months before admission he was admitted to another hospital because of a severe attack. There had been no hemoptysis. He was discharged after eleven days, feeling considerably improved. Since that time he had continued to grow weaker and more exhausted. He had had occasional night sweats for an undetermined period of time.

Twelve years before entry his wife died after sanatorium care for tuberculosis of the sacroiliac joint. An eighteen-year-old daughter was living and well.

As a youth he had worked for several years in a dusty cardboard-box factory. Two years before admission he had worked for several months in a boiler room shoveling soft coal. He had had a mild chronic "cigarette cough" for about ten years, which im-

*On leave of absence.

proved when he stopped smoking three months before entry.

Physical examination revealed a poorly nourished, well developed, pale man with signs of recent weight loss. There was no lymphadenopathy. The chest was barrel shaped and showed diminished expansion. There were moderately fine rales at both bases posteriorly, extending higher on the right side. In the axillary line bilaterally there were some high-pitched musical rales. The heart border was not percussible, but the heart sounds were of fair quality. A blowing Grade 2 apical systolic murmur was heard.

The temperature was 98.6°F, the pulse 115, and the respirations 20. The pulse soon returned to about 90. The blood pressure was 100 systolic, 70 diastolic.

Examination of the blood showed a red-cell count of 4,000,000, with 80 per cent hemoglobin, and a white-cell count of 10,700, with 74 per cent neutrophils, 12 per cent lymphocytes and 14 per cent monocytes. The urine was acid, with a specific gravity of 1.015, a trace of bile and a rare white cell. A sputum specimen showed no tubercle bacilli. The stool was brown, and guaiac tests were positive.

FIGURE 1 *Roentgenogram of Chest*

but was not transmitted to the axilla. The abdomen was scaphoid, with an old operative scar in the right upper quadrant. At each end of the scar was a depression, the lower one having some dried exudate around it. To the right of the scar opposite its midpoint was a firm movable mass in the abdominal wall, this could not be reduced. On coughing, other viscera herniated into the pouch and lodged beside the permanent mass. Distinct epigastric tenderness and spasm were more marked on the right than on the left. No other masses were felt. One observer noted right pleural-angle tenderness.

Tuberculin tests in dilutions of 1:100,000 and 1:10,000 were negative. A blood Hinton test was negative.

X-ray films of the chest showed both lungs to be involved in a grossly nodular process, with a network of increased density connecting the more miliary nodules (Fig. 1). In addition there were areas of emphysema in the right lower lung and a few rarefactions suggesting cavities in the upper lung fields, particularly on the right. The heart was small but otherwise not remarkable. An electrocardiogram was consistent with coronary heart disease.

The serum nonprotein nitrogen was 36 mg per 100 cc with subsequent lower values, and the total protein 7.8 gm, with an albumin-globulin ratio of 0.88, the chloride was 98.0 milliequiv per liter, and one week later 85 milliequiv. The prothrombin time was 30 seconds (normal, 18 to 20 seconds). An oral Graham test was tried but the dye failed to pass the pylorus and outlined a distended stomach.

The patient was extremely weak and constantly tired. On the fifth hospital day the temperature became elevated and remained between 100 and 102°F for four days. Thereafter for about a week the oral temperature was between 97 and 98°F. On the sixth day he had an episode of what was thought to be paroxysmal auricular tachycardia, with a pulse rate of 160, which reverted to normal rhythm spontaneously in about twelve hours. A gastrointestinal series on the sixth hospital day revealed a normal esophagus. The stomach was atonic and contained fluid and retained food. Fluoroscopically there was thought to be a shallow ulceration on the lesser curvature just below the angulus. After transient prepyloric spasm the duodenal cap filled out well and appeared normal. The upper small intestine was not remarkable. The diaphragm moved equally well on both sides. Two days after the gastrointestinal series a gastric lavage yielded large amounts of barium. At that time numerous rales were heard throughout the chest and the patient stated that the lavage made him short of breath. A sputum culture was negative for beta-hemolytic streptococci and pneumococci.

On the eleventh hospital day the patient began to cough up blood-tinged sputum and a few particles of what appeared to be necrotic tissue. Frequently repeated smears for tubercle bacilli were negative, and a pathological examination on the sputum sediment revealed no tumor cells. A gastroscopy on the fifteenth day showed superficial gastritis with multiple erosions. The patient was relieved by daily gastric aspirations after the twentieth hospital day. He then appeared to have repeated attacks of pyloric obstruction, and approximately 1000 cc of foul-smelling, dark-brown, guaiac-positive, thick fluid was obtained with each aspiration. On the twenty-first hospital day the temperature, pulse and respirations began to rise, the temperature fluctuating between 100 and 103.5°F.

On the twenty-second day the patient became markedly dyspneic and apprehensive. The abdomen was distended. Peristalsis was present. The spleen was not felt. The liver was thought to be large. The blood chloride was 77 milliequiv per liter, and the total protein 4.5 gm per 100 cc. A van den Bergh test was 0.9 mg per 100 cc direct, and 1.2 mg indirect. On x-ray examination the appearance of the chest had not changed appreciably.

The patient became progressively weaker, more

dyspneic and ashen-gray despite an oxygen tent. His lungs were filled with rales, and he expired on the twenty-fifth hospital day.

DIFFERENTIAL DIAGNOSIS

DR JOHN W. CASS: The initial statement in this man's history makes one think of cancer of the stomach more than anything else. If cough were added, one would think of tuberculosis. The post-operative story is that of a patient with a residual empyema of the gall bladder, a draining sinus and the subsequent development of a ventral hernia. The history indicates a transition into a progressive illness, with localization in the chest as well as in the abdomen. The asthma by itself is not significant, since it could have been a symptom of a general disease. A malignant lesion of the chest is not uncommonly ushered in by attacks of asthma, and tuberculosis is not infrequently accompanied by asthmatic attacks.

We learn that there was a family history of tuberculosis, which suggests that perhaps the whole story was accounted for by tuberculosis. Contact is the one thing that one searches for, and here it can be established.

I know of no occupational hazard connected with a cardboard-box factory or with shoveling soft coal.

The physical examination again localizes the disease to the chest and to the abdomen. It brings into the picture a mass, which was not the hernia and which was not related to the sinus tract. The laboratory work indicates an obvious secondary anemia. The blood smear showed 14 per cent monocytes, which is not helpful by itself but is suggestive of tuberculosis. The trace of bile in the urine we have to accept as a pathological finding that incriminates the liver. The tuberculin tests are interesting. Negative tests with dilutions of 1:100,000 and 1:10,000 are rare in an adult of fifty, but in these dilutions they cannot be considered negative. The test should have been done with a dilution of 1:100. A negative tuberculin test in a man of this age is so rare that one might suspect he had some form of tuberculosis in the terminal stage.

May we see the x-ray films?

DR GEORGE W. HOLMES: There are two obvious things in this man's chest. He has a wide antero-posterior diameter and a low diaphragm—the characteristic appearance of an emphysematous chest. In addition he has a diffuse process that involves both lungs, the right more than the left. There is a suggestion of a cavity in the right apex. It is not definite enough, however, for me to say that it is a cavity, so that I am not particularly helpful. If it is a cavity, we have to consider carcinoma, tuberculosis and silicosis, although I should think that the last was unlikely.

DR. CASS: The x-ray report says "miliary nodules." Are they nodules or tiny cavities?

DR. HOLMES: I suppose they meant small nodules. I do not recognize that as a customary expression.

DR. CASS: Are they blebs or cavities?

DR. HOLMES: I do not know. Part of the chest is blurred, but there is probably some fluid in the pleural cavity.

DR. CASS: In the lateral films is there any evidence of bone change?

DR. HOLMES: No.

DR. CASS: There was a gastrointestinal series mentioned in the protocol.

DR. HOLMES: The films are not helpful.

DR. CASS: There was a statement about previous ulceration.

DR. HOLMES: I think that we have to take that for what it is worth. I am not able to demonstrate anything on the films. It was a fluoroscopic note.

DR. CASS: So the x-ray picture is that of a nodular, miliary process, not one of small cavities. The presence of a large cavity is questionable. The likeliest diagnosis is tuberculosis or a malignant neoplasm, pneumoconiosis or sarcoid being rather poor bets.

The nonprotein nitrogen was normal, which is surprising in a man so ill. The total protein was high and the albumin-globulin ratio was low when he came in. Later, the low protein and increased prothrombin time suggest intrinsic liver damage.

The paroxysmal auricular tachycardia does not help. There is no evidence that we are dealing fundamentally with a heart condition. Dr. Holmes says that we have to accept the statement that there was a gastric ulceration, but the most information we get is that there does not seem to have been any gross intrinsic disease of the stomach. There was ulceration, but it was not characteristic enough to make one think of tumor.

A real but unsuccessful effort was made to find acid-fast organisms. There was no evidence of tumor cells, at least in a single specimen. Gastroscopy helps in making us think that we are dealing, so far as the abdomen is concerned, with obstruction of the stomach. It could have been due to a pathologic process close to the pylorus or it could have been secondary to the hernia. In general the abdominal situation seems more compatible with tumor than with tuberculosis.

In the terminal days of the patient's course there was a marked change in the blood chemical findings, which is again compatible with a good deal of intrinsic liver disease. But we are dealing with a patient with extreme debility and malnutrition, and the laboratory work may not be too significant. It is important that there was no significant change in the x-ray films of the chest.

In summing up the situation, it seems to me that the picture is that of a wasting disease with localization both in the chest and in the abdomen, and

that in the beginning the difficulty was chiefly in the liver. So far as the chest is concerned, there was a diffuse nodular miliary process. The tuberculin test was negative, at least in dilutions of 1:10,000, as were sputum studies, so that the process in the chest is more compatible with tumor than with infection. I did not mention actinomycosis. That does give a nodular appearance, but it seems to me that the evidence narrows down to tuberculosis or tumor. So far as the abdomen is concerned, there were positive findings of gall-bladder empyema, with a draining sinus, a large liver, no jaundice and laboratory studies indicating a good deal of intrinsic liver damage. The pyloric obstruction, so far as we can tell, was extrinsic and could have been due to pressure from a mass in the region of the gall bladder or bile ducts. There may have been a rupture of the abdominal process into the chest, so that from a diagnostic point of view, we have to decide, first, whether we are dealing with tumor or infection and, second, whether there were two diseases.

It seems to me that if we can logically connect the two it is safer to make one diagnosis than to make two, and the weight of evidence seems to me to be in the realm of a malignant tumor. If so, where did it lie? We know that in patients with chronic draining sinuses for this length of time malignant degeneration is liable to develop in the sinus tract or gall bladder. Malignant disease in these areas usually metastasizes to the chest. If the process in the chest was nodular, it is compatible with metastatic malignancy, although one cannot rule out tuberculosis, particularly that of the miliary type. By far the safest diagnosis is malignant tumor developing in the region of the gall bladder, with metastases to the liver and lungs.

A PHYSICIAN: Would someone comment on the low chloride?

DR. FRIEDRICH W. KLEMPERER: It was probably due to the vomiting, with consequent loss of chloride.

DR. E. FREDERICK ALSTON: I should like to ask about the significance of the elevated monocyte count. Does this occur with many types of prolonged illness?

DR. CASS: There is a pouring out of monocytes in many types of infection, such as undulant fever and tuberculosis. A single reading of that number, however, does not help me in the diagnosis one way or another, it does, however, suggest tuberculosis.

CLINICAL DIAGNOSIS

Carcinomatosis

DR. CASS'S DIAGNOSIS

Carcinoma of gall bladder, with metastases to liver and lung

ANATOMICAL DIAGNOSES

Acute pulmonary tuberculosis (miliary).

Adenocarcinoma of head of pancreas, with metastases to regional lymph nodes, stomach, liver, abdominal wall and lungs

Tumor thrombi in lungs and liver.

Tuberculosis of bronchial lymph nodes

Pleuritis, acute fibrinous, with effusion

PATHOLOGICAL DISCUSSION

DR. BENJAMIN CASTLEMAN The autopsy on this man showed a bizarre picture in the lungs. There was 300 to 400 cc of turbid fluid in each pleural cavity. Both lungs were replaced by yellowish miliary areas of necrosis, some of which were confluent and frankly caseous. Many of the blood vessels were plugged with grayish-white material that looked like tumor thrombi, and this was confirmed microscopically by frozen sections. In the head of the pancreas, just away from the common duct, was a firm granular grayish-white mass, 4 cm in diameter, which was the primary tumor. The liver was riddled with tumor, which had replaced from one third to one half the parenchyma. Here also, as in the lungs, the blood vessels were involved, and the portal vein radicals within the liver were filled with tumor thrombi. Our final sections of the lungs showed that in addition to the carcinoma there was true caseation, and stains for tubercle bacilli showed myriads of organisms. It is almost inconceivable that they were not found in the sputum, since they could be picked out in our sections even under low power. We were unable to find tuberculosis in the sinus tract of the old scar. There was a large tumor nodule beneath the scar, which was a metastasis to the abdominal wall. The tumor proved to be an adenocarcinoma. There were metastases to the regional nodes around the pancreas, some of which had infiltrated the wall of the stomach, so far as we could tell these had not broken through the mucosa, although a number of superficial mucosal vessels containing small bland thrombi were eroded. There was some blood in the stomach, but we could find no evidence of tumor. I imagine that the pressure of the metastatic nodules on the vessels had caused the thrombosis and the subsequent erosion.

CASE 31372

PRESENTATION OF CASE

A seventy-six-year-old widower was admitted to the hospital because of urinary frequency and nocturia.

During the previous six months, overflow dribbling had progressed to spontaneous and uncontrollable voiding, and during the two days before entry he was able to void only a few drops at a time.

There had been no pain, hematuria or previous acute retention.

He had had no venereal disease and no other serious illness, except for typhoid fever about four years before entry.

Physical examination revealed a well developed, well nourished man who appeared well and in moderately severe distress after catheterization. The teeth were in poor repair, and there had been many extractions. The lungs were clear and resonant, with normal breath sounds. The heart was not enlarged. The rate and rhythm were normal, and no murmurs were heard. Examination of the abdomen was negative, except that the liver edge was approximately two fingerbreadths below the right costal margin. A rectal examination revealed an enlarged prostate. The median sulcus was present, and the right lobe felt smooth, soft and about two times the normal size. The left lobe was considerably more prominent than the right, measuring approximately 5 by 3.5 cm, and was quite firm and rubbery. A tense, somewhat fluctuant 1-cm mass was palpated on the lateral aspect of the left lobe. The extremities were negative.

The temperature was 100.5°F, the pulse 80, and the respirations 20. The blood pressure was 140 systolic, 75 diastolic.

Examination of the blood showed a white-cell count of 7000 and a hemoglobin of 75 per cent. The serum protein was 5.3 gm per 100 cc, the acid phosphatase 1.4 units, and the alkaline phosphatase 1.6 units. The nonprotein nitrogen was 34 mg per 100 cc, and the phosphorus 2.4 mg. A blood Hinton test was negative. A catheter specimen of urine was grossly bloody, with a specific gravity of 1.024, and gave a +++ test for albumin. Urine cultures showed *Staphylococcus aureus*, and three consecutive blood cultures yielded *Staph aureus*, all the blood-culture strains were coagulase positive. The organism was found to be penicillin sensitive.

On the second hospital day the patient was cystoscoped. The mucosa was red and edematous. The median and both lateral lobes of the prostate were large and projected into the bladder. The testes were normal. The right vas deferens was slightly thicker than the left, and the globus minor of the right epididymis was swollen, tense and extremely tender. On the third day penicillin therapy was begun, and on the fourth day a suprapubic cystostomy was performed. The temperature, which had been spiking daily to 103°F, returned to normal, the pulse, which had been between 90 and 110, became normal on the fifth day, and the respiratory rate, which had risen to 45 on the third day, returned to 20. The white-cell count rose to 13,400, and the hemoglobin to 85. On the sixth day the nonprotein nitrogen was 60 mg per 100 cc. From the fourth to the ninth day the patient appeared much better and progressed favorably in preparation for a prostatectomy.

During the forenoon of the ninth day he had a sudden chill. The rectal temperature rose to 103.5°F but returned to normal in four hours. The pulse rate was elevated to 110, and the respirations rose to 40. That evening there was slight edema of the ankles. There was moderate dyspnea, and moist crackling rales were heard at both bases. There was no pleuritic pain or signs of consolidation. A loud rough systolic murmur lasted throughout systole, it was heard over the entire precordium but was loudest over the apex. A precordial thrill was felt. X-ray examination on the following morning showed indistinct heart borders due to considerably increased density that extended throughout both lung fields, radiating from the hilar areas into the lungs, this was most marked in the lower lung fields. The density appeared to follow the vascular markings. A small amount of fluid was present in the pleural sinuses. No evidence of infarcts was seen.

On the ninth day the serum nonprotein nitrogen was 42 mg per 100 cc, and the protein 5.3 gm. On the tenth day digitalization was begun. Late that afternoon the patient complained of a vague chest pain. In the evening he experienced sudden distress. He became more dyspneic, orthopneic and cyanotic. He insisted on sitting on the edge of the bed and had a sensation of impending doom. The peripheral pulse was extremely weak, and the skin cool and clammy. The pain in the chest radiated down both arms, and the dyspnea became rapidly severer. The chest was full of loud moist rales, and the heart sounds were distant and irregular. Within thirty minutes of the onset of the distress he expired.

DIFFERENTIAL DIAGNOSIS

DR. PAUL D. WHITE: The urinary difficulties indicate prostatic obstruction. I am not able to relate the typhoid fever to the present story.

This man apparently had a normal heart at the time of entry into the hospital, so far as one can tell from the physical examination. The liver edge was approximately two fingerbreadths below the costal margin, but that was probably due to a low position rather than to enlargement. The prostate was firm and rubbery, apparently not so hard as would be the case in cancer. The fluctuant mass suggests an abscess, of course. The urinary findings seem to be in keeping with prostatic enlargement and infection. The acid phosphatase is within normal range, but that does not rule out cancer of the prostate. Only an increased acid phosphatase would suggest cancer and that is not the case here.

Were any blood cultures taken after penicillin therapy was begun?

DR. BENJAMIN CASTLEMAN: The last blood culture, taken on the fourth hospital day, was positive.

DR. WHITE: And penicillin was given on the third day and continued thereafter. I note that a chill occurred despite the penicillin. How much was given?

DR. CASTLEMAN: Ninety-six thousand units a day.
DR. WHITE: In divided doses, not by drip? That is an important point.

DR. CASTLEMAN: He was given 12,000 units every three hours.

DR. WHITE: I wonder why he had an elevation of the nonprotein nitrogen. Perhaps it was due to renal involvement. The clinical appearance was in keeping with the drop in temperature, pulse and respirations, despite the elevated white-cell count.

This patient, who previously had shown no murmurs or thrill, abruptly developed an unusual cardiac murmur and thrill. I wonder how loud the murmur was. We have had a successful experience in the last year or two, largely owing to close contact with Dr. Samuel A. Levine when re-examining Army cases, with the classification of heart murmurs from Grades 1 to 6. This murmur might have been the type that one can hear with the stethoscope actually off the chest, that is, Grade 5 or 6. It was at any rate a significant murmur.

Are the x-ray films here?

DR. C. HALE: All the pulmonary vascular markings are prominent, and there is also a diffuse haziness.

DR. WHITE: There are no areas suggesting infarction or consolidation?

DR. HALE: I do not see any.

DR. WHITE: The heart is not particularly enlarged. The aorta looks all right for a man of seventy-six.

The nonprotein nitrogen came down terminally, and therefore the patient did not die of uremia. Digitalis was begun the day after the acute complication arose. On the basis of the x-ray findings, it was evidently thought that digitalis was needed. The patient had pain for the first time on the tenth day. The acute illness on the ninth day was not accompanied by pain, — at least there is no statement about it, — but there were dyspnea, a chill and edema of the ankles and lungs. Where was the distress that he suffered on the evening of the tenth day, which was evidently much severer?

DR. CASTLEMAN: Chest pain is all that is recorded.

DR. WHITE: A sense of impending doom is not a reliable symptom in patients who have heart trouble. Nervous persons with simple paroxysmal tachycardia may have a sense of impending doom, whereas people actually dying usually have no such sense. Still, the symptom may be significant here, for he was extremely sick and we may judge by inference that the pain or distress was severe.

In review there are several things that seem clear. Whether there was a prostatic tumor, I do not know, I doubt it. The prostatic infection, possibly retrograde to the bladder and kidneys, was present to start with, and following that came a *Staph aureus* septicemia, which in turn was followed by acute heart failure.

The episode on the ninth hospital day was at-

tended by what sounds strongly suggestive of mitral regurgitation of an unusual nature, probably the result of rupture of a mitral valve cusp or chorda tendinea, secondary to acute bacterial endocarditis. Such a thing could have happened in the course of a week or two, the endocarditis having been silent for a while. Endocarditis due to *Staph aureus* infection is, as a rule, extremely severe and rapid in its course. Other causes of such a murmur with thrill seem less likely. Dilatation of the left ventricle, without structural change, under the stress of illness of any sort may give a murmur, but it is not so pronounced as the one that was found here.

Perforation of the ventricular septum from infection might have occurred, but one would expect that the murmur and thrill would have been nearer the sternum than they were. A rapidly developing aortic stenosis, with large vegetations, should also be mentioned as a possibility but not a probability. Metastatic carcinoma involving the heart is less likely than infection. Complicating septic infarcts of the lungs must be considered, but the electrocardiographic findings do not favor an acute cardiac strain (cor pulmonale) from that source. Thus, bacterial endocarditis, with rupture of a valve cusp or chorda, best explains what happened on the ninth day.

On the tenth day something else happened that precipitated death. This sounds like an acute coronary occlusion, which caused death in half an hour. He had severe chest pain radiating down both arms, with collapse. Pulmonary embolism is unlikely. Coronary atherosclerosis is the most frequent cause of coronary occlusion, but it is more intriguing, of course, to try to fit the picture into one piece. Hence I suggest the possibility, or indeed the probability, of acute coronary embolism due to vegetations on either the mitral or aortic valve. Dissection of the wall of an infected aorta and rupture of the heart wall itself from abscess, with cardiac tamponade, should be mentioned as diagnostic possibilities but they are not likely.

I will stand on the diagnoses of prostatic abscess, *Staph aureus* septicemia, acute heart failure secondary to acute bacterial endocarditis with rupture of the mitral valve or one of its chordae and, finally, acute coronary embolism.

DR CASTLEMAN Dr Smith, you saw this man, would you like to comment on the urinary infection?

DR G GILBERT SMITH The only thing that occurs to me is that he might have had an abscess in the left lobe of the prostate.

DR CASTLEMAN Dr Segall, have you anything to add?

DR HAROLD SEGALL One interesting possibility is that the murmur might have occurred as a result of infection, or infarction, of the myocardium with involvement of the papillary muscle and rupture there. Cardiac rupture frequently starts at the

base of the papillary muscle. In the course of twenty-four hours extension proceeds from the base of the papillary muscle until it reaches the pericardium, this sometimes happens in half an hour.

DR WHITE But he had no pain.

DR SEGALL In old people it may start silently, and the first thing you know the heart has ruptured.

CLINICAL DIAGNOSES

Benign prostatic hypertrophy
Coronary thrombosis

DR WHITE'S DIAGNOSES

Prostatic abscess
Septicemia (*Staphylococcus aureus*)
Acute bacterial endocarditis (*Staph aureus*)
Ruptured cusp or chorda tendinea of mitral valve
Acute heart failure
Terminal acute coronary embolism

ANATOMICAL DIAGNOSES

Acute bacterial endocarditis, with mycotic aneurysm of aortic valve and rupture of commissure between right and left posterior cusps
Adenocarcinoma of prostate
Pylonephritis, mild left kidney
Abscess of epididymis, right

PATHOLOGICAL DISCUSSION

DR CASTLEMAN At the commissure between the right and left posterior aortic cusps was an ulcerated granular thrombosed vegetation that had produced a rupture of both cusps (Fig 1). This ulceration had extended through the commissure as a small mycotic aneurysm, 1 cm in diameter, this had involved the myocardium of the right wall but had not perforated through the endocardium. Perhaps if the patient had lived a few days longer it might have perforated. Each of these cusps had a frayed edge, so that there must have been free regurgitation.

DR WHITE Was the mitral valve all right?

DR CASTLEMAN Yes.

DR WHITE The murmur must have been diastolic, not systolic. The record fooled me.

DR CASTLEMAN There was no involvement of the coronary arteries, unless perhaps a bit of the vegetation on a cusp might have partially covered one of the coronary mouths. It would have had to extend into the right coronary orifice, and at the time of autopsy this was free of disease.

DR WHITE How do you explain the final episode?

DR CASTLEMAN There is only one way that I can think of. Perhaps one cusp frayed on one day and the other on another day.

DR WHITE But there must have been a diastolic murmur, with a diastolic thrill. The examiner obviously timed the murmur wrongly.*

dominant diastolic murmur, owing to flapping of these torn cusps in regurgitation. Do you not agree, Dr Segall?

FIGURE 1

DR SEGALL That could happen if the rate was rapid.

DR WHITE If there was free aortic regurgitation without aortic stenosis there must have been a pre-

DR SEGALL Yes.

DR CASTLEMAN There was no real stenosis.

The remainder of the heart was negative. The prostate was enlarged and quite hard. Microscopically it proved to be an adenocarcinoma. There was an abscess in the right epididymis, and mild pyelonephritis on the left.

*Examination of the record revealed no checkup of the timing of this murmur by internists on the hospital staff. Rupture of an aortic cusp always causes a diastolic murmur, whereas rupture of a mitral cusp or chorda causes a systolic murmur.

SURVEY OF HOSPITAL FACILITIES

THE American people have been told that the United States needs more hospitals, that existing hospitals in many localities need more beds and that large sections of the country are without adequate hospital service. The reports on which these statements are based have been compiled by various organizations, including the American Public Health Association, and although the facts that they present are undoubtedly correct, the conclusions drawn are open to question.

A lack of hospital facilities, where it exists, is linked in almost every instance with a similar lack of medical service—that is, the absence of hospitals deters doctors from practicing in those areas, and

vice versa. There is no use in having hospitals without competent doctors to staff them. The two must be correlated.

When a physician is confronted with a medical problem he first collects his facts, weighs them, makes his diagnosis and then determines the course of treatment. That is just what the people of the United States want to have done regarding the hospital and medical situation in their respective states. Furthermore, they wish to have this done on a local or state basis, because they believe that their respective states are too big to be satisfactorily treated by a single prescription, even though they desire a co-ordinated national plan.

With this in mind and through the efforts of the American Hospital Association, the Commission on Hospital Care was established last year, being supported by grants from the Commonwealth Fund, the W. K. Kellogg Foundation and the National Foundation for Infantile Paralysis. The objectives of this commission are to take a census of the present hospital and public-health facilities in the Nation, to appraise their capacity for service, to establish standards for evaluating physical facilities, organization and management of hospitals, to determine the overall national need for additional facilities and service, to formulate a national, co-ordinated hospital plan and to suggest methods by which that plan can be realized.

National interest in this survey is already widespread. Thirty-five states are in one phase or another of their studies, and surveys are actually in operation in Iowa, Massachusetts, Michigan, Minnesota, New Hampshire, North Dakota and Wisconsin. Each state is urged to carry on its own study, since in this way local interest will be aroused, each state will become aware of its need, and a desire to furnish adequate service will be stimulated. The commission will act as a co-ordinating body and will furnish a standard questionnaire, as well as technical consultants, for the use of all states making the survey. The final job of tabulation will be done by the commission's staff.

In Massachusetts, Governor Tobin has appointed a committee, headed by Dr. Vlado A. Getting, Commissioner of Public Health, to carry on the survey. A budget has been submitted and will probably be

approved by the Legislature. Certain hospitals have been asked to fill out the standard questionnaire, to gain experience before submitting it to all hospitals.

The efforts of the Commission on Hospital Care, operating on a voluntary basis in true democratic fashion and supported by private funds, bid fair to be supplemented by the passage of a bill (S 191) now before Congress, which would amend the Public Service Act "to authorize grants to states for surveying their hospitals and public-health centers and for planning construction of additional facilities, and to authorize grants to assist in such construction." If passed, the bill would immediately provide \$5,000,000 to assist state surveys and would allocate \$100,000,000 available on June 30, 1946, for the construction of public and other nonprofit hospitals. These two sums could be appropriated each succeeding fiscal year for the same purposes, as determined by Congress. The Surgeon General of the United States Public Health Service would be authorized to make such regulations as are necessary to administer the bill. He would consult with the Federal Advisory Council, consisting of himself, as chairman *ex officio*, and eight members appointed by the Social Security Administrator. States applying for assistance would be required to designate a single state agency as the sole means for carrying out such purposes, provide a state advisory council, meet standards prescribed by the Surgeon General and approved by the Federal Advisory Council and agree to make reports as requested by the Surgeon General. If these requirements are complied with, allotments both for surveys and for construction would be based on the respective state population and financial need, ranging from 25 to 75 per cent of expenditures. Incidentally, essentially the same provisions are included in the Wagner-Murray Bill (S 1050).

The present situation is that state surveys of hospital and public-health facilities are being encouraged and aided by the foundation-supported Commission on Hospital Care. They may possibly be financially aided by the federal government. In any event, knowledge of hospital needs and what is to be done about them should be materially advanced.

THE EPIDEMIC OUTLOOK IN EUROPE

DISEASE and pestilence have always been known to flourish during large wars, to follow in their wake and to add to their ravages. Fresh in the minds of many of us are memories of the great pandemic of influenza that occurred near the end of World War I, of the great toll taken by the epidemic of typhus fever that spread through the Balkans during and after the war and of the other widespread epidemics in eastern and southern Europe that followed it. Although tremendous strides have been made in the prevention of disease in the American armed forces and in those of some of our allies, the outlook for serious epidemics among the European populations in the near future is gloomy. Such is the conclusion arrived at by Knud Stowman* in an analysis recently published by the UNRRA.

Several important factors have led to this pessimistic attitude. When the war came to an end, the civil administrations in most of the countries that are likeliest to be affected were in a fluid state and many of them are apt to be so for some time to come. Even more significant are the mass migrations that gained momentum during the latter phases of the war and still continue. The displaced persons include war prisoners, refugees, slave laborers and those who survived the horrors of the concentration camps. Not only are most of these persons in a condition that makes them highly susceptible to epidemic diseases, but they constitute a serious reservoir of infections, which they will carry back to the native lands to which they are repatriated.

Some of the most dangerous diseases that it is feared may be introduced into previously unaffected areas have already made their appearance to a varying extent in the Mediterranean area, the Near East, North Africa and Dakar. They include plague, smallpox and typhus fever. Yellow fever and cholera have thus far shown no tendency to spread, although an outbreak of the latter disease has been recently reported among the natives in Chungking. On the other hand, the more commonly occurring infectious diseases, such as cerebrospinal meningitis, poliomyelitis, typhoid fever, dysentery, diphtheria and scarlet fever, have all shown a twofold or threefold increase during the war years. This is

*Stowman K. Epidemic outlook in Europe. *Brit. M. J.* 1 742-744 1945

apparently a greater increase than was observed in World War I. Furthermore, the incidences of some of the endemic diseases, such as malaria, syphilis, gonorrhea and tuberculosis, have increased many-fold and at a greater rate than that during the previous war.

Dr. Stowman believes that the absence of any real disasters thus far is due, in part, to the low endemic levels of disease in the years immediately preceding the war. The rapid increases in these diseases during the war, he thinks, serve as an index of what may be expected. The vast destruction of homes, especially in the densely populated cities, together with the great population shifts, when added to the increased prevalence of the common infectious and endemic diseases, makes the outlook for large epidemics in Europe even darker than it was after the last war. The only encouraging feature, which tends to offset those fears somewhat, is the fact that we are now better equipped to prevent and cope with some of these problems. In addition, our knowledge of existing situations is far more complete. Dr. Stowman concludes his analysis with the following pertinent remarks:

On the public health front, World War I lasted not four but more nearly ten years. However, it was gloriously won. Many years of effort in combating infectious diseases have once more been lost so far as Europe is concerned. To make up for backsliding will take several years after the cessation of active hostilities, but the public health profession and services can win their war now as then.

MASSACHUSETTS MEDICAL SOCIETY

DEATH

BARTLEY—John J. Bartley, M.D., of Lawrence, died June 16. He was in his seventy-fourth year.

Dr. Bartley received his degree from Harvard Medical School in 1901. He was Lawrence city physician from 1908 to 1909 and supervisor of school physicians there at the time of his death. He was a member of the Lawrence Medical Society.

His daughter survives.

MEDICOLEGAL ABSTRACT

Medical Schools What standards are to be used in granting approval, adoption of AMA standards. In a recent decision in the New Jersey Supreme Court the action of the New Jersey State Board of Medical Examiners in passing on the application of a graduate of Middlesex University School of Medicine of Massachusetts for licensure was considered.

The graduate, who had been licensed to practice medicine in Massachusetts, sought to compel the

State Board of Medical Examiners to license him to practice in New Jersey by virtue of his license to practice in Massachusetts or, in the alternative, to admit him for examination for license in New Jersey. The application was denied because the applicant had not met the statutory requirement by graduation from a medical school approved by the State Board of Medical Examiners.

The court said in part:

The question to be determined is whether the respondent is justified in classifying Middlesex University School of Medicine as an institution which was not in good standing. It appears that it bases its conclusion in the grading and standing of medical schools on the standard adopted by the Committee of Education of the American Medical Association and makes public the names of the schools which it approves. It is argued by the relator that the action of the respondent in accepting the grading of medical schools by the American Medical Association is without using its own judgment or discretion but constitutes an unlawful delegation of its duty and power. We think not. It is entirely within its discretion, it seems to us, to adopt the standard and grading of an organization of which it has knowledge and confidence. We think it acted within its sound discretion within the meaning of the statute *supra* and was not actuated by arbitrariness or capriciousness. — (*Rothsied v. State Board of Medical Examiners*, 132 N. J. L. 38, 38 Atl. 2nd 444 [1944])

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

PLANS FOR A NEW DENTAL DIVISION

A division of dental health in the Massachusetts Department of Public Health will be created on July 1, 1946, subject to legislative approval of funds for the new division.

It is planned that Lieutenant Colonel Francis B. Carroll, of Waban, will become director of the division. Dr. Carroll is at present with the First Service Command. Prior to that he was with the Department of Public Health as district health officer in the Pittsfield area.

The director and assistant director will be centrally located in Boston and will have technical supervision over dentists and dental hygienists attached to the district offices.

The objectives of the division will be to stimulate more effective dental care of preschool and school children through official and voluntary agencies, to initiate educational projects in dental health in schools, service clubs and other organizations, to assist in special field studies and to inspect dental clinics.

Dr. Carroll graduated from Tufts Dental School and then took postgraduate work in public health at Harvard. After attending medical school at the University of Rochester he engaged in full-time public-health work with the Kellogg Foundation in Michigan, later becoming district health officer with this department. For several years he practiced dentistry in Whitinsville, where he specialized in children's work.

THE DIAGNOSIS AND TREATMENT OF CYSTITIS IN WOMEN AND CHILDREN*

HERMAN L. KRETSCHMER, M.D.†

CHICAGO

BY THE term "cystitis" is meant an inflammation of the urinary bladder characterized by frequency of urination, painful urination and pus in the urine. It should be remembered, however, that this clinical triad does not always mean cystitis *per se*, and it is because of this fact that a large number of errors in diagnosis occur.

Although cystitis *per se* in the female — either young or old — is an exceedingly rare condition, the triad of symptoms generally interpreted as indicative of cystitis is extremely frequent in occurrence, with the result that the diagnosis of cystitis is often made but is rarely substantiated. Many patients who present themselves with this symptom-complex are incorrectly diagnosed and incorrectly treated, the serious organic lesions that are the real cause of the condition being overlooked until late in the course of the disease, when conservative surgery becomes impossible owing to the destruction of vital organs.

As a matter of fact, to impress these facts on the minds of students, I frequently make the statement that, in my experience, cystitis in women and children is one of the rarest lesions I encounter, and that for purposes of early diagnosis it should be assumed that cystitis in the female is nonexistent. Furthermore, when symptoms indicative of cystitis are present and no improvement occurs within a reasonable time after medical treatment has been instituted, or when symptoms clear up only to recur at a later period, it becomes imperative that the patient have a complete physical and urologic examination. The most important problem that confronts one when dealing with this type of case is not the administration of this or that drug but the making of an accurate diagnosis to determine the nature and location of the lesion responsible for the symptoms.

The History

The importance of obtaining a good history in each case of so-called "cystitis" cannot be over-

emphasized. An accurate history cannot be obtained hurriedly by an office nurse, and all too often scant attention is given to this. The information obtained generally more than compensates for the time and labor expended.

One must bear in mind that a patient with symptoms of cystitis may be suffering from a lesion in some remote part of the body — that the bladder symptoms may be an expression of a distant disease process. In this category may be placed diseases of the blood, such as pernicious anemia. As an example of a patient belonging to this group, the following case is presented.

A 65-year-old woman, 6 weeks before she was seen by me, had marked frequency of urination and pain on urination and was told there was pus in the urine. A diagnosis of cystitis was made at that time, and treatment consisted of internal medication, bladder irrigations with boric solution and injections of argyrol into the bladder. The patient consulted me for the express purpose of having her bladder washed out.

Examination of the urine was negative. The physical examination showed the knee jerks to be greatly exaggerated, with clonic reactions. Romberg's sign was positive, and the patient walked with some unsteadiness.

The diagnosis, based on the blood examination, was pernicious anemia with secondary degenerative changes in the cord.

Symptoms may be erroneously ascribed to cystitis when they are in truth due to the presence of a congenital anomaly — a condition that in some cases can be readily ascertained by careful history-taking. The following case illustrates the value of obtaining a painstaking history.

A 27-year-old woman was admitted for the relief of what she had been told was cystitis. She stated that she was unable to hold her urine, lost urine between urinations and had been wet all her life. For the relief of her complaints she consulted many doctors and received various forms of treatment, without relief. The treatment included urethral dilatation, applications of silver nitrate to the urethra, instillations and irrigations of the bladder and, finally, dilatation of the bladder.

A careful consideration of one of the patient's statements — namely, that she was unable to hold her urine between urinations — at once suggested the possibility of an ectopic ureter. Examination showed the presence of such a ureter just behind the external urethral orifice.

The onset of symptoms of cystitis after a surgical operation has great significance. Bladder symptoms

*Read at the annual meeting of the New Hampshire Medical Society, Manchester, New Hampshire, May 16, 1944.
†President, American Medical Association.

following an operation are often attributed to cystitis, treatment is instituted without relief, and the patient begins a pilgrimage from one doctor to another. Fortunate she is if the correct diagnosis is eventually established. The patient's statement that the symptoms of the so-called "cystitis" were absent before the operation should at once direct the doctor's attention to the possibility that the operation was a factor in the bladder disturbance.

A history of cystitis given by a patient who has spent part of her life in a sanatorium for tuberculosis, by one who has had repeated attacks of pleurisy or by one with a record of repeated tapings for pleural effusions must at once arouse suspicion that one is dealing with a case of renal tuberculosis with a secondary tuberculous cystitis. A thorough clinical investigation should be made in all cases before beginning local treatment.

In cases in which the patient gives a history of recurring attacks of cystitis, one's suspicion should at once be aroused that some underlying factor is responsible for the recurring attacks, and it is of paramount importance to determine just what that factor is. Not until it has been determined should treatment be instituted. In a certain number of these cases, the recurring cystitis can be traced to a pyelitis or to an infected hydronephrosis.

In some cases of colon-bacillus infection of the urinary tract, with symptoms of cystitis, it may be possible to obtain a history of disturbance in the intestinal tract. As a matter of fact, it is surprising how frequently constipation or cathartic colitis is the causative factor, hence, the importance of directing attention to the intestinal tract before instituting urologic treatment is self-evident.

Physical Examination

The examination should first be directed to the patient as a whole. Although tabes dorsalis is rare in women, the presence of an Argyll-Robertson pupil, absent knee jerks and the presence of Romberg's sign are strong indications that the cystitis is one of the manifestations of locomotor ataxia.

Scars in the neck, the aftermath of suppurating cervical adenitis, evidence of active or healed tuberculosis of the lungs and the presence of an ankylosed joint or scars over bones, the result of long-standing suppuration, must be given very careful consideration in the interpretation of every case of so-called "cystitis." Nor must it be forgotten that other general disease processes are often associated with frequency of urination. It is not unusual to find during the course of the physical examination that the patient suffers from cardiorenal vascular disease, as a result of which there is frequency of urination both during the day and night. In this group of patients, if the urine is free of pus and sterile on culture, the relation between the underlying disease and the cystitis is perfectly obvious. On the other hand if the urine, although grossly clear, shows a

few pus cells and the culture reveals colon bacilli, great care and study are needed to arrive at the proper conclusion.

After the physical examination follows the local examination. This should include a careful examination of the external urethral orifice and Skene's glands. The urethra should be palpated and the strippings examined for pus. A catheterized specimen of bladder urine should be obtained.

With the bladder empty, one should proceed with an examination of the internal genitalia. Vaginal discharge, so often present, should be carefully examined for the presence of *Trichomonas vaginalis*, which is occasionally found in women who are being or have been treated for cystitis. The urine should also be examined for this organism. Next in order is an examination of the cervix and of cervical discharge, if present. Finally, a pelvic examination should be done. It is surprising how often in this group of cases disease is found in the uterus, tubes or ovaries.

One must be careful, however, not to jump at a wrong conclusion and attribute the so-called "cystitis" to pressure from an enlarged fibroid, for it should be borne in mind that a patient may have two lesions, either of which may be responsible for the condition. Double lesions are of relatively frequent occurrence, for example, I saw a patient afflicted with a fibroid and an elusive ulcer and another with a fibroid and renal tuberculosis. Here, as in any other branch of medicine, great care must be exercised in the evaluation of the physical examination.

Lesions in and about the anus and rectum are often the cause of so-called "cystitis." This possibility must be considered in every case before a diagnosis is made.

Lesions of the bowel, such as diverticulitis with peridiverticulitis, may produce bladder symptoms. Here again, only too often the diagnosis is erroneously made.

Examination of Urine

Having obtained a catheterized specimen of bladder urine before the pelvic examination is made, one should proceed to a careful urine examination. When pus has been found in a voided specimen of a woman or girl, nothing other than the examination of a catheterized specimen should satisfy the physician.

If the specimen so obtained is negative and a tentative diagnosis of cystitis has been made, it is imperative that the examination be repeated several times. With symptoms of cystitis present, the urinary examination should determine the presence of albumin, blood (by chemical and microscopic examination), pus cells, red cells, casts and crystals. The urinary sediment should be examined with a methylene blue stain and a gram stain for the presence of bacteria. Finally, no examination of the

sediment is complete without an examination for tubercle bacilli. A part of the catheterized specimen, at the time it is obtained, should be sent to the laboratory for culture.

At this point in the examination of the patient, an appraisal of the mode of procedure should be made. This, I wish to emphasize is to be interpreted as a consideration of the order in which the next steps are to be performed — not as a means of avoiding them. These steps must be carefully carried out in this group of cases in order to make an accurate diagnosis and to determine whether one is dealing with a true case of cystitis or with a case of so-called "cystitis."

Röntgenographic Examination

The x-ray examination may precede or follow the cystoscopic examination. A flat plate of the urinary tract should be made. In a good many cases this is negative, on the other hand, the presence of a shadow in the juxtavesical portion of the ureter compatible with stone, calcifications in the renal area due to stone or calcifications due to renal tuberculosis are extremely informative.

Whether an intravenous pyelogram should be made at this time depends on the history and the results of the examination up to this point. If it is done before the cystoscopic examination, information of great value may be obtained. It is to be remembered that errors in interpretation are frequent and often costly and have led to wrong conclusions. For example, failure of the kidney pelvis to visualize does not necessarily mean congenital absence of the kidney, nor does it mean that the kidney has been destroyed by disease.

Cystoscopic Examination and Ureteral Catheterization

The presence or absence of cystitis must rest on the result of the cystoscopic examination. If this is negative, it is reasonably certain that the patient who is referred with a diagnosis of cystitis does not have it and further study to determine the cause of the symptoms is in order.

Because cystitis in women and children is rare, it is imperative that no patient be treated for this condition for any length of time without a cystoscopic examination. Nevertheless, one sees many patients who have been treated from one year's end to another without a cystoscopic examination's having been made. Should this examination show the presence of an abnormality in the bladder, such as a stone, foreign body, tumor or ulcer, the appropriate treatment can be started at once.

If on cystoscopic examination the bladder is negative, as happens in a large number of cases, the upper urinary tract must be investigated by means of ureteral catheterization. In a large number of cases the primary lesion is found in the kidney. Among the various lesions of the kidney that may

be overlooked for a long time because of the presence of symptoms of cystitis is tuberculosis.

It is a well-recognized fact that in cases of renal tuberculosis frequency of urination is often the first symptom of which the patient complains. Frequency of urination may be due to the presence of tuberculous pyelitis, in which case the cystoscopic examination is negative. When the patient is finally subjected to a careful urologic examination, extensive tuberculosis of the bladder may be found and the bladder may be contracted to such a degree that even after the kidney has been removed and the tuberculosis of the bladder healed, the frequency of urination continues because of the limited bladder capacity. Drugs and bladder irrigations give no relief from the bladder symptoms, in fact, the condition is often made worse by bladder irrigations. When the correct diagnosis has finally been made, such extensive changes have taken place in the bladder that a complete return to normal bladder function is no longer possible.

After the ureters have been catheterized and a specimen of urine taken for a leukocyte count, gram stains, routine and tubercle-bacilli cultures and guinea-pig inoculations and a phenolsulfonephthalein test has been made, a set of retrograde pyelograms may be taken. Whether this should be done depends in part on whether intravenous pyelograms were made before the cystoscopic examination, as well as on the result of the precystoscopic examinations of the urine for tubercle bacilli and the cystoscopic findings. If tubercle bacilli are found or there is reason to suspect renal tuberculosis, retrograde pyelograms should not be made.

Some of the lesions that must be considered in the differential diagnosis of cystitis are listed in Table 1.

Treatment

Once the diagnosis of the underlying lesion responsible for the symptoms has been made, the treat-

TABLE 1 *Lesions of the Urinary Tract To Be Considered in the Differential Diagnosis of Cystitis*

Urethra	Radium burns
Acute urethritis	Foreign bodies
Chronic urethritis	Cystocele
Stricture	Postoperative distortion
Diverticulum	Ovarian cysts
Skenitis	Ovarian carcinoma
Polyps	Cysts of the parametrium
Benign tumors	Lesions of the gastrointestinal tract
Carcinoma	Fissure
Prolapse	Hemorrhoids
Bladder	Carcinoma of the rectum or colon
Elusive ulcer	Diverticulitis with or without rupture
Tuberculosis	Chronic cholecystitis
Stone	General Disease Processes
Polyps	Nephritis
Trichomonas infestation	Diabetes mellitus
Stone	Tabs dorsalis
Carcinoma	Fernicious anemia with cord changes
Incrusted cystitis	
Perivesical adhesions	

ment is perfectly obvious and needs no detailed discussion. It naturally varies, and is as diversified as is the list of possible causes of cystitis just presented.
